On the other hand, if one considers situations of refutation, the perspective of individual scientists may show great variation. The modern historian does try, therefore, to reconstruct *all* that “was in the air” at the moment in *all* research communities, whether expressed in documents or not. Within a particular scientific community—usually a fairly small group—there may be many things in the air: a more or less generally accepted theory formulated in a fairly definite way (at that moment); the report—interpreted in slightly different ways and involving some explicit auxiliary hypotheses—of a case of observational disconfirmation; several attempted modifications of the theory that seem to change the chains of derivations in such a way that the awkward prediction cannot be made; and several attempted modifications of auxiliary hypotheses or assumptions “disconnecting” the (unaltered) theory from the unfavorable observational report. Whatever the momentary decision of each member of the group, the multiplicity of factors will *continue* to “be in the air.” Decisions not yet published are easily revoked—a long sequence of happenings may take place before anything is published and matters are stabilized. Sometimes interest will contract and subside before satisfactory results can be reported to the community at large: the disconfirmation has been duly recorded and will be remembered, but little can be done about it. Scientists just continue applying and working with the theory—if there is no alternative at the time.

It is a consequence of the foregoing that there are no crucial experiments in the sense of experiments not only furnishing a set of negative instances, but automatically furnishing decisive and definite refutation in the strong sense of furnishing rational justification for rejection.

However, “a new look at crucial experiments” has convinced Imre Lakatos that crucial experiments can “overthrow research programs.” But it is clear that it is not the cognitive basis of this (causally defined) overthrow, the isolated negative instances, that are crucial, but rather the whole development following on the experiments. If there is no “come-back, after sustained effort . . . the war is lost and the experiment proved, with hindsight, ‘crucial.’”⁹ This is a sound description, especially when hindights are dated, so that it does not look as if there had been a definite *last* hindsight. But it does not touch on rejection or definitive refutation as a cognitive, nonvolitional notion.

II

Experimental Setup, Rank Dimensions, and Pluralism

Decisive Relevance of Experimental Setup to Testability, Field of Test, and Cognitive Content of a Theory

Contemplating the history of genetics, Bentley Glass poses a question of relevance far outside his own speciality:

The important thing to note in this connection is the effect of the overwhelming well-nigh universal acceptance of a conceptual model that explains satisfactorily all—or nearly all—of the scientific data now known. One must recall that the doctrine of the “billiard-ball gene,” the conception of the “chromosome as a string of beads,” likewise had a tremendous weight of experimental evidence in its favor and little to render it invalid or even slightly dubious, until evidence of a new kind began to accumulate in the past twenty years. Today, graduate students and young geneticists, like those of a generation ago, accept without question the *current dogma*, mould their thinking round it, and most importantly, plan their experiments in accordance with it. Is it not conceivable that, for all its virtues, the blind acceptance of a conceptual model may once again, as so repeatedly in the past, hinder the advancement of science towards a deeper appreciation of genetic relationships?
(Glass 1963: 539)

The abdication of the old model or theory in the case described by Glass was preceded by an accumulation of *evidence of a new kind*. The area of relevant, practicable tests is in general near zero in extension compared with the field of relevant tests. If there is prolonged, diverse, and successful testing within the practicable field, however small, a theory tends to be unanimously accepted. But only among those tending toward dogmatism is it considered to be *true*. The transition from acceptance of a theory while working with it—that is, when using, applying, elaborating it—to accep-

tance of it *as true* has no function in research activity. Among dogmatists it diminishes production of ideas incompatible with the theory. A certain kind of tyranny is established where dogmatists are in charge of research policy. The “life expectancy” of a theory largely depends on the rate of production of “promising” incompatible ideas and the energy with which they are elaborated and tested *independently* from the generally accepted theory.

Let us inspect in more detail the process of testing a theory, having in view the picture suggested by Pierre Duhem. It is my contention that we should make a model that takes into account all presumably relevant traits of the experimental situation (presumptions that may all be more or less misleading!). Each kind of test involves a *unique kind of experimental setup*. The descriptions of kinds of experimental setups are not part of the *exposition* of the theory, but as soon as there is a question of testing or applying it, they act on a par with genuine parts of the theory. At any given time there is a field of practicable experimental testing. The fate of the theory is in part dependent on what happens within that field. And the field is only describable in terms of families of experimental setups or designs. The clear understanding of the relevance of the differences of test operations to the cognitive content of the theory was an important factor leading Percy Bridgman toward his operationalism. Only by more or less arbitrary postulates can we be said to test “the same” things, for example, temperature or pressure when using vastly different test operations suitable for vastly different temperatures or pressures. The postulates are the bridges between molecular or quantum theory and kinds of experimental setups. A small modification of the postulates may alter the conclusion or decision; a presumably “heavily disconfirmatory instance!” may become a “confirmatory instance!”

If some of the relevant properties of the experimental conditions in given cases of testing are unknown, or if some of the relevant properties are not considered, the test is a partial or total failure. Neither confirmation nor disconfirmation ensues. In the life history of theories, this is the way that vast collections of “observations,” “data,” or “facts” drop out. Certain relevant traits of the experimental setups are no longer considered to be known, or they are considered to be known but to show lack of control of relevant variables (temperature, pressure, gravity, etc.). The criteria of relevance change, thus making whole libraries obsolete, as in the field of experimental psychology. A *critique* of the ways a theory

has been *tested* may leave the theory “naked”—that is, neither the reported confirming nor the reported disconfirming instances are accepted as relevant.

If, in this painful situation, new or improved experimental designs are not constructed, the theory is either abandoned without being “refuted”—a frequent event in the history of science—or it is heavily modified. This happened, for instance, to theories about various “experimentally confirmed” sensations in rats in the first two decades of this century. Another example is the rejection of vast collections of published data on degrees and kinds of *attention* when it became clear from more recent studies of suggestibility that the positive results of tests to a large extent reflected suggestibility on the part of the subjects. But the theories to be tested were theories of attention, not suggestibility! (Cf. Charles Spearman 1937, chapter on attention.) By considerable change of wording, the experiments *might* be taken to furnish positive instances of tests of theories on suggestibility. The weakness of this example for our purposes is that the “theories” were somewhat crude, more like empirical laws. A simpler example is the discarding of data on temperatures in the history of physics because thermometers used before certain inventions had been made were influenced by differences in air pressure.

In the case of quantum theory, a subclass of statements on experimental setups acquires a special status, as has been made abundantly clear by Niels Bohr.

[N]o result of an experiment concerning a phenomenon which, in principle, lies outside the range of classical physics, can be interpreted as giving information about independent properties of the objects, but is inherently connected with a definite situation, in the description of which the measuring instruments interacting with the objects also enter essentially. This last fact gives the straightforward explanation of the apparent contradictions which appear when results about atomic objects, obtained by different experimental arrangements, are tentatively combined into a self-contained picture of the object.

(Quoted in Müller-Markus 1966: 78)

Narrow Contextual Testing of Hypotheses

It was the contention of Duhem (1962: 188 ff.) that one cannot test an *isolated* hypothesis experimentally because in order to arrive at a definite

conclusion, one must assume the truth of other hypotheses, namely those making up the entire theory of which the hypothesis is a part.

Let H_1 be a hypothesis we intend to test, and H_2, \dots, H_n hypotheses assumed true or valid when testing H_1 , whether forming part of the same theory or not. Let the letter O symbolize a directly testable observational consequence (“methodological prediction”).¹

We can then illustrate verification and falsification of the hypothesis H_1 as follows, if S stands for H_2, \dots, H_n :

- (1) $[(H_1 \& S) \supset O] \& O$ (confirmation)
- (2) $[(H_1 \& S) \supset O] \& \sim O$ (disconfirmation)

By (1) we shall say that hypothesis H_1 gets *confirmed*. But this does not, of course, rule out that H_1 is false. And the confirmation is—if we ignore the intention of the experiments—not only of H_1 , but of a group of hypotheses. In its actual use among researchers, the term *confirmation* and similar, more idiomatic words are used in relation to H_1 even if the users themselves are perfectly aware of the role of some or all of H_2, \dots, H_n . The intention is built into the use, and only by neglecting this can one agree with Duhem.

As researchers, we *trust* H_1 if there are many and varied previous confirmations, but we may accept H_1 as a working hypothesis even if no confirmations, or only disconfirmations, are available, or if neither confirming nor disconfirming instances exist.

The formula (2) illustrates an instance of disconfirmation. According to current usage among researchers, it is a disconfirmation of H_1 , not of $H_1 \& \dots \& H_n$. That is, the definiteness of intention relative to the use is not sufficient to declare that the users clearly would reject (or accept) the suggestion that the disconfirmation is of *all* the hypotheses H_1, \dots, H_n . Cautiously I shall say that the instance of disconfirmation is of H_1 . Until further notice, I leave out of consideration the relation of the disconfirmatory process to the hypotheses H_2, \dots, H_n , since this is a separate issue.

From (2) we may conclude that H_1 and S cannot *both* be true—that is, that not *all* H_1, \dots, H_n are true:

- (3) $\sim(H_1 \& \dots \& H_n)$

This in turn is equivalent to:

- (4) $\sim H_1 \vee \sim H_2 \vee \dots \vee \sim H_n$

Whether it is H_1 or any other H that is not true remains unclarified.

In short, hypotheses are not verifiable or falsifiable separately, but only contextually, if at all. The expressions “instance of observational confirmation of H_1 ” and “instance of observational disconfirmation of H_1 ” do not refer to verification or falsification, but to the intended test of H_1 as part of a group of hypotheses from which (methodological) prediction is made. Confirmation does not preclude falsity, nor disconfirmation truth.

In the light of the above consideration, we may reformulate the Duhemian contextual principle of testing as a principle of falsification in this way: a hypothesis can only be falsified contextually, not in isolation. If we have an instance of observational disconfirmation but decide to continue to work with the hypothesis, we can justify our decision (in part) by making the ad hoc assumption:

$$(5) \quad \sim H_2 \vee \sim H_3 \vee \dots \vee \sim H_n$$

The relative strength of assertion of (5)—considered as a formula—is very little when n is big, and this suggests that the assumption is very weak.² But this nevertheless makes the case of disconfirmation irrelevant for H_1 . We can thus blame the wrong observational consequence on the rest of the test hypotheses, without necessarily specifying which of the H 's, H_2, \dots, H_n , we suppose to be untenable.

Implicit in the current usage of the term *disconfirmation* is, as already suggested, a reference to an intention: every single, definite experimental design is adjusted to *one* hypothesis, or to a group that is a (genuine) subgroup of the total class of hypotheses relevant to the test. One cannot have a design such that all relevant hypotheses are tested at once. If this were practicable, confirmation (or disconfirmation) would be confirmation (or disconfirmation) of all components taken separately.

The question of the methodological justification for (5)—that is, for blaming the unwanted happening on “the others”—can only be decided, if at all, on the basis of a study of the total research situation. What is the strategy at the research frontier at the moment? What are the priorities? Which are the interesting alternative hypotheses, if any? What can be neglected until further notice, considering the order of priorities? Making move (5) does not imply any definite *belief* that some of the other hypotheses are wrong. Position (5) may be posited as an ad hoc assumption in order to explore what might follow.

A Broad Thesis on Contextuality of Testing

I shall now propose a wider thesis of contextuality of testing than that of Duhem. His thesis is limited to the context of *other hypotheses* in the capacity of being other parts of the systematic exposition of a science. The context I shall refer to includes that of “initial conditions.” At least in part the sentences expressing such conditions do not express hypotheses belonging to the systematic exposition. The relevance of such a context has often been pointed out, and I shall only try to clarify some details.

The mass, position, and velocity of a planet at a given time must be specified before an observational prediction can be made by means of the Newtonian theory of gravitation. Any error here spoils a test of the theory. That is, if ten sentences express the initial state, the truths of all of them are presumed when the verdict of “confirmed” or “disconfirmed” is proclaimed. The formula $PV/T = r$ (P = pressure, V = volume, T = temperature, r = a constant) immediately prescribes three assertions to be tested, one stating the pressure, the other the volume, the third an indication of temperature. Considered as a hypothesis, $PV/T = r$ by its very formulation *prescribes* (at least) three initial-condition assertions.

This is all elementary. But a vastly greater number of factors are relevant to the conclusiveness of a test. In its textbook formulation, a law need not contain reference to gravitation or air pressure. But it is implicitly assumed, perhaps, that the law only holds true outside strong gravitational fields or in a near-perfect vacuum. If an observational report were to make all the relevant, more or less doubtful assumptions explicit, there would have to be a sentence reporting air pressure during the test and the local force of gravitation. Sentences of this kind are sometimes said to express the *Randbedingungen* (boundary conditions) of the test. They then include as a subgroup the specifications of the so-called *initial state* of a system, the initial-condition sentences.

Many famous tests have been inconclusive because of the uncertainty or vagueness or incorrectness of the initial-condition sentences. The researcher has had, for instance, to use very bad measurements of the size of the earth or the distance to the moon in testing gravitational hypotheses. Later some nonecholalic historians would say that the hypothesis was “really” correct but the experimental setup was imperfect, or the “constants” used were wrong. One is reminded of Newton’s temporary aban-

donment of his universal law of gravitation: he had assumed that a degree of the earth's circumference was only sixty miles in length. The measurement appears as one of the constants assumed to be correct in the description of the case tested. In other cases, a hypothesis *is not* given up. Thus, the existence of the neutron was persistently assumed in spite of strong negative experimental results. Referring to certain test situations, the discoverer of the neutron, James Chadwick (1932: 692), says: "The failure of these early experiments was partly due to the weakness of the available source of polonium, and partly to the experimental arrangement, which, as it now appears, was not very suitable." That is, if somebody *now* set up an experimental arrangement of this early kind and announced a disconfirmatory instance in relation to the existence of a neutron, one would point to certain unfulfilled requirements specified as *Randbedingungen* (boundary conditions) in later experiments. The hypothesis no longer covers experimental test situations of the old kind.

There are no rules such that one can or must pick out a definite set of traits of the experimental setup and express them in *Randbedingung* sentences. What is certainly required and what may certainly be left out depend on characteristics of the problem situation at the frontier of research, and only insiders can develop such an awareness. The novice betrays his crudeness in counting trivialities and leaving out essentials. If, say, $s = \frac{1}{2}gt^2$ is to be tested, one must of course specify in initial-condition sentences g and t , s and t , or s and g . But which special features of the mechanical setup should be mentioned? Scientists are apt to refer only to those features that they think or guess members of the research community would find particularly relevant when asking about the *quality* of the experiment. But the identity of the experiment is only in part determined by those features. The choice of factors considered relevant and worth mentioning is always in part the result of sociological guesswork.

I shall distinguish, in what follows, narrow or central initial-condition sentences from peripheral initial-condition sentences. The adjective *central* I shall reserve for the assertions related to constants prescribed by the very formulation of the hypothesis. The *peripheral* initial conditions have two important properties in common: (1) They do not belong to the hypothesis intended to be tested nor to any other hypothesis derivable from the same theory, nor do they belong to the narrow or central set of initial sentences on conditions. (2) If a categorical verdict of "confirmed" or "discon-

firmed” is made, the truth or correctness of these assertions is assumed. If any of them are false, the test is irrelevant; it has, strictly speaking, no weight in relation to the question raised (until it is perhaps calculated *how much* the state of affairs expressed by the negation of the assertions could influence the experimental conditions).³

By “initial conditions” I shall refer to the total class of central and peripheral assertions.

In different philosophies of science, opinions concerning the scope and variety of (relevant) peripheral conditions must necessarily show variation. The new historiography must be expected to accept a very broad concept. The longer the periods of development studied, and the more weight laid on periods of revolution, the more kinds of conditions will have to be taken into account. But this holds good only insofar as the new historiography aims at covering *different* philosophies of science. It calls for a neutrality that is difficult to reach, even if strongly coveted.

Referring to the conflict between cosmologies at the time of Galileo, Feyerabend seems to insist on ideas or theories of cognition being considered part of the initial conditions (in my terminology):

The Copernican view conflicts with the evidence that has been established in accordance with the older ideas of cognition and is directly compared with it. This is not a relevant test. Relevant tests must interpolate meteorological, dynamical, and physiological disturbances between the basic laws and the perceptions of the observer.
(Feyerabend 1970c: 294)

I certainly agree but might add that parts of theories of cognition that are relevant to the testing of any hypothesis whatsoever, and affect all in a similar way, might not be counted as initial conditions.

Taking central initial-condition sentences (*I*), into consideration, we now write for purposes of illustration:

- (6) $[(H_1 \ \& \ S \ \& \ I) \supset O] \ \& \ O \ \& \ I$ (confirmation)
- (7) $[(H_1 \ \& \ S \ \& \ I) \supset O] \ \& \ \sim O \ \& \ I$ (disconfirmation)

In the case of disconfirmation, our suspicion may center on any hypotheses contained in *S* or on some of the many sentences, *I*, specifying initial conditions and, of course, on the professional level of the observation itself or on the complicated transition symbolized by \supset .

We also need a formula reminding us of the importance of the truth of the description of the experimental setup. Perhaps there was no vacuum? Perhaps the light patch was due to an imperfection in the lenses?

In what follows, the letter *E* stands for the conjunction of the peripheral initial conditions. The truth of *I* and *E* is a necessary and sufficient condition for the relevance of the maximum of the experiment.

The explicit derivation of *O* is usually made without stating anything about the experimental setup. This is presumably the main reason why it is customarily omitted from presentations of “logic of science.” The sentences expressing the setup appear as an addition to the others before the decisions “confirmed!,” “disconfirmed!,” or “undecided!” are taken. We may now write:

$$(8) \quad [(H_1 \& S \& I) \supset O] \& O \& I \& E \quad (\text{confirmation})$$

$$(9) \quad [(H_1 \& S \& I) \supset O] \& \sim O \& I \& E \quad (\text{disconfirmation})$$

Any change in truth-value of any sentence expressing the test situation (the *E*’s) will result, according to (8) and (9), in there being neither confirmation nor disconfirmation. We get an “undecided!”

Theory of cognition must include theory of observation. Since the time of Hermann von Helmholtz’s discussion of the nature and limitations of scientific observation, more or less precise and careful theories of observation have been developed. But situated as they are at the crossroads between physics, chemistry, biology, physiology, and psychology (and other social sciences), these theories have not been easy to compare and evaluate.

Because of the inevitable proliferation of theories of observation, the class of observations of a phenomenon is only a (roughly) definite class (at a definite stage of the movement of the research frontier) if related to a definite theory. The classes related to different theories sometimes have, sometimes do not have, common elements. Those who subscribe to a theory of pure sense-data will tend to say that if scientists note down in their observational journals *exactly* what they observe (that is, sense-data) and then count as observed phenomena only phenomena *defined* by the observations in the journals, then there will be an invariance in the class of observations in relation to competing theories. But in spite of very advanced work in defense of theories of sense-data and in spite of related

theories of “the immediately given,” no such theories have been established. In fact they are even losing ground. So we must, I think, admit that as things stand now, there are, strictly speaking, extensive variations in the elements of classes said to constitute “the observational basis” of a theory.

Only rarely is there such a large-scale agreement as in the case of “the red shift.” Here what we *observe* are displacements of spectrum lines—that is, differences in measurable locations of lines (usually on a photograph), but because of the large number of theoretically important kinds of complications that arise when interpreting the differences, there is a general and pronounced modesty about what is said to be observed. Usually it is the displacements that are said to be observed, not, for instance, the velocity of bodies receding from us. That is taken to be an *interpretation* of a displacement.

Suppose we have a theory, T , which says that under specified conditions of the kinds $A(x)$, $B(y)$, . . . we should observe certain values of the two parameters (variables) $F(z)$ and $G(t)$. If, for instance, x and y are 6 and 8, we derive from T that z and t should be 3 and 2. In addition to x and y , there will be an indefinite number of other specified conditions—“indefinite” because of the indefinite number of elements of the class “relevant traits of the experimental (or more generally, observational) setup.” Only a few of them will be quantitative, as $A(x)$ and $B(x)$.

The recognition, identification, and acceptance of F and G as *phenomena observed* (that is, that something is such and such) depends on views, mostly unexplicated, about observation. When made explicit and precise, the views may take different forms. Let us say T_1 is the adopted form. It will be our *theory of observation*. The choice of A , B , . . . as explicit parameters of conditions depends on a set of auxiliary hypotheses, assumptions, and postulates.

Thesis: Given (1) a set of observations said to be observations of a definite phenomenon, (2) a theory said to be a theory covering that phenomenon, and (3) a set of auxiliaries used as intermediaries between the theory and the observations, then if T_1 is a theory of observation that, together with a set of auxiliaries, justifies (or permits the derivation of) the conclusion that the phenomenon *said* to be observed is the phenomenon observed, one may always formulate a workable observation theory, T_1 , incompatible with, or even incomparable to T_1 , such that it, together

with a set of auxiliaries, justifies (or permits the derivation of) the conclusion that the same observations (in the form of symbols in an observational journal) are of a different phenomenon.

In short, *what we identify as the phenomenon observed* depends on our theory, or rather metatheory, of the process of observation. Given the potential many-one relation of workable theories to phenomena said to be observed, there will never, as long as active research in the field continues, be one phenomenon uniquely pointed out by any theory.

Whether this thesis is judged tenable or not seems largely to depend on which field of research one habitually works in. For workers in psychophysics, perception, and many other humanistic disciplines, the thesis is considered true, but more or less trivial. “Tough” natural scientists tend to ignore or reject it.

Much of the importance of the thesis is due to its sobering effect: whereas the Mach-Duhem-Poincaré principle (see p. 37) stresses the many-one relation between theories and observation to be covered, the above thesis stresses the many-many relation between metatheory of observation and phenomenon said to be observed.⁴ For *a given theory* T' , the relation may be represented thus:

Figure 1. Illustration showing the many-many relation between metatheories of observation and their corresponding observed phenomena for a single theory.

Theory T' , combined with metatheory (of observation) MOT^* , results in O^* being taken as the observation under a specific set of conditions. Combined with metatheory MOT^{**} , the same theory under the same conditions results in O^{**} being taken as the observation. The term “observation” is here used to express something that includes the identification of a phenomenon observed (for instance, “2 °Fahrenheit,” not just “2”).

The corresponding many-many relation may, for *two competing theories* T' and T'' , be illustrated as follows:

Figure 2. Illustration showing the many-many relation between metatheories of observation and their corresponding observed phenomena for two competing theories.

Here, from two mutually inconsistent theories T' and T'' , the same observation is derived. But close inspection suggests that a metatheory MOT^* is presumed. So the observation is symbolized by O^* rather than simply O . If a different metatheory, MOT^{**} , is assumed to be valid, the “same” observation must be given the form (and content) O^{**} .

It remains to illustrate the application of a metatheoretic principle of the Mach-Duhem-Poincaré type to these theories of observation. It implies that, for instance, MOT^* would not be the only metatheory that together with T' yields O^* :

Figure 3. Illustration showing the many-many relation between multiple metatheories of observation and their corresponding observed phenomena for two competing theories. Metatheories whose names have the same number of asterisks but different indices, have the observations under consideration in common but are in other respects different. Metatheories named with a different number of asterisks cover different sets of observations.

The multiplicity of metatheories of observation precludes that we can, strictly speaking, identify a set of observable phenomena independently of a metatheory of observation. As long as all scientific observers within a field have a similar cultural background, the implicit views on observation may be expected to show small variation. Explication is often unnecessary. However, an interplanetary research team, including some strange beings from α Centauri, might pose some tough problems of metatheory.

According to the foregoing, an instance of confirmation or disconfirmation of a hypothesis by observation is only definable relative to a fairly complex conceptual structure. The relata are the other hypotheses of the theory to which the hypothesis belongs, S , the central and peripheral initial conditions, I , the sentences that guarantee the relevance of the experiment, E , and the observation theory MOT^* .

We may illustrate the above by offering the following schemata for such instances:

- (10) $[(H_1 \& S \& I) \supset O^*] \& MOT^*(O^*) \& E \& O^*$ (confirmation)
- (11) $[(H_1 \& S \& I) \supset O^*] \& MOT^*(O^*) \& E \& \sim O^*$ (disconfirmation)

Philosophers of science of so-called empirical affiliations have something to learn from the *praxis* theoreticians, for the latter do not identify the empirical with the observational. There is ample historical justification for a broader interpretation of “empirical”: the Greek word may well be translated as “experiential.” My experience as a human being includes my professional experience and all I have of experience outside my profession. I am more “experienced” in relation to certain tasks than in relation to others, and the difference reflects both personal and social conditions. Observation also contributes to my experience but cannot be severed from the rest as more basic or more certain.

“It is my experience that . . .” This locution is convenient for reference both to observations and to informal, crude generalizations and interpretations of what one has “seen and heard,” as well as to *tentative expressions of insights* that integrate both.

When more instances of observation are unlikely to overthrow a theory, more experience may well do the job. Conditioned reflex theories covering learning of mazes were undermined by broad, relaxed, critical reflections and observations on rats running in mazes. Environmental factors and the experimental designs were tentatively changed. Some theo-

rists were able to assess more clearly the narrowness of the standard conditioned reflex experimental setup. They had *enlarged their experience*. Radical criticism of the dominant conditioned reflex theories was made possible.

The expression “observation falsified or weakened the theory” can, thanks to the eminent metatheoretical work of a large number of philosophers of science, be given very precise and interesting reformulations. The expression “experience falsified or weakened the theory,” taking “experience” in broader meanings than “observation,” has not been worked on with similar admirable results. I shall not try here to change the situation. Suffice it to say that the situation calls for an integration of the empirical and *praxis* models of cognition, using the wide connotations of experience as a point of departure.

Plurality of Functions and Rank Dimensions of a Theory

What are the prospects of fulfilling the purpose, the intended functions, after a negative result of the test of a theory? What are the alternatives? Are other theories available? If not, what is the prospect of creating alternatives?

Perhaps the scientist, if he is of an unusually articulate subspecies, can list, say, ten functions relevant for him and make up his mind about the change in the prospect of the theory’s fulfilling those functions after the setback. If philosophers of science were interested in honest, down-to-earth investigations of reasons why individual scientists abandon or continue to work with a theory or a hypothesis, they would have to start with such reasons mentioned by the scientists themselves and then start trying to classify, simplify, and criticize.

Incidentally, a methodologist of social science, Johan Galtung (1967: 459), lists ten dimensions of theories, all of them “rank dimensions in the sense that they can be used to evaluate theories”: (1) generality, (2) range, (3) status of individual hypotheses, (4) formalization, (5) axiomatization, (6) relations to other theories, (7) predictability, (8) communicability, (9) reproducibility, and (10) fruitfulness.

Some readers might look for “testability” as a dimension. It is indirectly taken into account by (3). The rank dimensions of hypotheses are said to be: generality, complexity, specificity, determinacy, falsifiability, testability, communicability, reproducibility, predictability, and tenability.

It should not be necessary here to discuss the number and kinds of rank dimensions of competing theories. Suffice it to remind ourselves that the intricacy and many-sidedness of the functions of a theory necessitate *a whole range of questions being asked* when assessing the status of a theory; insofar as these questions allow for improvement in interpersonal preciseness, they are best thought of as part of a comprehensive questionnaire. The pretesting of the questionnaire would probably result in eliminating such predicates as “works well,” or “is simple.” Very different abilities are placed together under the heading “works well,” and “simplicity” has recently been used in too many senses.

With ten rank dimensions, not necessarily those suggested by Galtung, ten competing theories may all score differently, each scoring satisfactorily in relation to some dimensions and unsatisfactorily in relation to others. In lively research communities, the comparative status of a set of competing ideas will show variation over the years. The action to be taken on the part of the active researchers in the face of this complex situation cannot easily be one of simple acceptance or rejection but must be considered within a long-range research strategy, with distant moves dependent on feedback from previous moves.

Today scientists work mostly in groups that belong to larger communities. Whether one drops a theory depends very much on what others do.

Why is it necessary to remind ourselves of the bewildering multiplicity of rank dimensions of a theory? First of all, because in this century ingenious but simple models on the metalevel have been worked out and then mistaken for reality—or at least have been discussed as if they pretended somehow to cover the actual function of theory choice. One cannot doubt the central importance in metascientific queries of simple models and rational reconstructions in general, but mistakes as to their operation (and limitation) may prove fatal to metaresearch. “Hypothetico-deductive method” is a name for models that have been mistaken for single descriptions.

A very weak disconfirmatory instance may, under certain circumstances, be a *conclusive or decisive* factor in rejecting a theory. The scientist decides to *stop working with it*. In the background of the simple words “He rejected the theory,” or “The theory was now abandoned,” there is, of course, a complicated *praxis*. Sometimes these words just mean that *for the moment*—that is, within a definite subsection of a research program a sci-

entist finds the prospect of work on the theory unpromising—or they may mean that a competing theory, which has already been worked out to some extent, seems much more promising to him in that particular work at that particular time. But at the same time others may find applications for the abandoned theory, acknowledging that it yields excellent predictions within many fields and may still be a potent source of inspiration when contemplating possibilities of new theories. (Cf. Bohr’s “Correspondence Principle” as a guide for the imagination.)

Scientific research is a search for truth, but this does not imply that the range of properties of rank dimensions of scientific theories is intuitive and uncontroversial. A drop in strength of assertion increases, or at least cannot decrease, chances of truth. But in spite of this, superior strength of assertion is taken as an argument *for* a theory, not against it. It figures prominently in rank dimensions. “Simplicity” is controversial: some take it to be part of an adequate set of rank dimensions; others do not (the disagreement is somewhat less than it seems because of semantical confusion). The dimensions must “have to do with truth,” but must also “have to do with search!”

It is of course an important goal to arrive by rational discussion at one single set of rank dimensions as the supremely adequate one in a particular historical research situation within a particular field.

But the prospect of this noble goal should not prevent us from admitting that we are very far from realizing it and that the best thing to do at present is to clarify discussion on criteria, connecting the disconnected strings of argumentation, to make key terms (“simplicity,” “observation,” “fact”) more precise in various directions, to refine the network of distinctions, and to deepen the range of explicit assumptions all the way down to fundamental ontological and other philosophical positions.

In judging the relative validity of proposed priority lists for rank dimensions of a theory, one has to take into account the typology of the intended main functions of theories. After all, most original and important innovators in science have their own way of conceiving the function of their theorizing.

A survey of broad theories, or rather systematizations, in the field of (theoretical) psychology in the 1930s suggests that they may be ranked according to a variety of traits deliberately fostered by the theoreticians. In the table on page 31 the systematizations are compared and ranked in

an intuitive way. The numbering of the following items corresponds to those of the several columns of the table.

1. High level of (verbal) explicitness and unambiguity as regards assumptions, and clarity as regards implications, whether genuine or not. (Conventional criteria—include, for example, prestigious physiological, physical, or mathematical terms and an abundance of “if . . . then . . .” and “according to that . . . this . . .” statements.)
2. Extent of the field (of possible predictions) *claimed* to be covered by the theory. (For example, certain experimental results, learning, and adaptive behavior.)
3. Unambiguousness in *practice*—that is, for use by independent observers: consistency of estimated implications by observers with different terminological or general ideological idiosyncrasies.
“Cooperational efficiency”: Suppose an observational report obtained under specified conditions is given. The greater the number of independent users who arrive at the same conclusion as regards the question of whether the report (1) is irrelevant to, (2) strengthens, or (3) weakens the theory, the greater the cooperational efficiency.
4. Extent to which we assume cooperational efficiency to have been due to factors other than positive transference among members of an ingroup. (We assume that in view of the absence of extreme degrees of clarity and rigor in any existing theories, consistency of implications is achieved by direct adaptation and “*Gleichschaltung*” of speech habits between members of the group.) If members of an ingroup are bound together closely by common slogans and habits of exposition and inference, the expansion of the group will make the theories cooperationally more clear because of the greater percentage of psychologists tracing out the implications in the same way. Thus, a minus in column (4) but a plus in column (3) means that the relatively high degree of cooperational efficiency is to a small extent reached by factors other than transference among members.
5. Ease with which an outgroup (a group of competing theorists or people with some training in psychology who do not belong to a definite theoretical group) can distinguish programmatic state-

ments and slogans from other statements, and the ease with which it is possible to separate programmatic (anticipatory, propagandistic) components of the meaning of a statement from other components. If reports of experiments are couched in a terminology toward which certain groups are hostile, this will make it difficult for members of these groups to see anything other than the odious terminology. The way to an understanding of the experiments and the results is thus made more difficult than would seem necessary. Another example is where propaganda by means of general slogans and broad methodological declarations is mixed so perfectly with specified descriptions and interpretations that outsiders do not know what is “serious” and what is “show.”

6. Extent to which predictions have been made from the theory in a cooperationally efficient manner. Same unit of measurement as under (2).
7. Preponderance of successes (verified predictions) among the predictions mentioned under (4). *Post-festum* predictions (“This result is just what I would have predicted from my theory if you had asked me”) are included if backed by those other than the author of the theory.
8. Author’s preference for concepts taken from the realm of “low-level” (*l*) behavior or “high-level” (*h*) behavior. (Examples: physiological behavior, stimulus mediation—low level; level of descriptions of behavior in the vernacular—high level.)
9. Type of methodological rationalization in cases of asterisks in column (8): *P* \equiv salvation of psychology as a science by low-level approach by “reduction” of high-level descriptions to low-level, by looking for possibilities of extension of physiological (ultimately physical) laws in the realm of high-level behavior. *C* \equiv salvation of psychology by finding laws (at least high statistical correlations, as in chemistry) that hold for high-level behavior, by adaptation of conceptual framework to the exploration for such “invariants.” Belief in ultimate reduction to low-level as explained under (7). *A* \equiv extreme antiphysiological attitude by stress upon the necessity of using sociological (or very high-level) descriptions of behavior in every case of specification of test conditions for a theory, whether the theory is conventionally called physical, physiological, or psy-

chological. Disbelief in reduction of high-level laws to low-level laws. Integration of science “from above.”

10. Emphasis in actually accomplished research on:

$L \equiv$ rigor. Theorem producers.

$F \equiv$ extent of field covered, imaginative (exploratory) fruitfulness of system. Hunch producers.

$S \equiv$ significance for social problems and reforms (rather than for “academic” problems). Social-argument producers.

The table below shows my scores of psychological systematizations from various points of view. A score of – means a small amount of the trait scored, + means a fair amount, and ++ means a large amount. An h means the system starts from “higher-level,” or “molar,” concepts; l means the system starts from “lower-level,” or “molecular,” concepts. An * means that the h or the l is especially stressed by the author of the system.

Types of Theories Compared

Brunswik	Theories on thing constancy
Freud ₁	Theories on psychoneuroses
Freud ₂	Theory according to which interruption in verbal reaction in the psychoanalytic situation is due to suppression rather than to lack of associations
Hull ₁	Gradient of reinforcement (goal gradient hypothesis)
Hull ₂	Revised mathematico-deductive theory of rote-learning (1939)
Lewin	Theory of psychological forces (1938)
Piaget	Studies on the cognitive development of children
Skinner	“Average” theory of <i>The Behavior of Organisms</i>
Thurstone	“Average” rational equations, theory of primary factors
Tolman ₁	Scheme of operational psychology (in his presidential address)
Tolman ₂	Sowbug theory of VTE (1939)

	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
Brunswik	–	++	–	+	–	–	+	h^*	S	F
Freud ₁	–	++	+	–	–	–	+	h		S
Freud ₂	+	–	+	–	+	–	+			
Hull ₁	+	++	+	–	+	–	+	l^*	P	L
Hull ₂	++	–	++	++	++	–	+			
Lewin	++	++	+	–	–	–	+	h		F
Piaget	–	+	+	+	+	–	+	h		F
Skinner	+	++	+	–	+	–	+	h		F
Thurstone	++	++	+	+	++	–	+	h		L
Tolman ₁	–	++	+	–	–	–	+	h^*	S	F
Tolman ₂	+	–	++	+	+	–	+			

As seen from the table, none of the theories considered has a + (or –) in every rank dimension. All of them have some advantages and some disadvantages. This suggests the complexity of choosing what theory is most promising. It also emphasizes the importance of establishing explicit value priorities in order to rationally reconstruct a policy choice.

But the creative scientist need not, of course, experience anything comparable to a cold *pro et contra* deliberation centering around a number of rank dimensions. This might happen, but usually the decisions for or against particular possibilities to theoretical solutions of a problem are experienced as violent “true or false” intuitions. Relevant criteria are closely connected with the special topic at hand, and not experienced as abstract principles applied to a concrete case.

Theories help us “solve problems.” This means first of all that we obtain understandable, integrated answers that address sets of burning questions—it is primarily the *kind* of answers we obtain that we use to judge the efficacy of the theory. How “certain” the solution is, is of course also a matter of consideration, but if the theory is not completely without zones of testability (cf. Einstein’s criterion) it is acceptable. When it is said that Schroedinger’s wave equation “completely solved” *the problem* of atomic hydrogen, what is meant is that questions covering the spectacular behavior of atomic hydrogen in electric and magnetic fields, questions relating to its spectral lines, and practically all other questions raised *at a certain time*, were answered by using Schroedinger’s equation. Where experimental checks were possible, they were fairly successful, but if some serious discrepancies had been found, they would most likely have stimulated theoretical interest rather than made physicists “reject” the theory (of which the equation was a part).

The expression “*x* completely solved the problem *y*” might suggest that if *x* is a theory it must show a high level of observational confirmation or rank very high on all dimensions. This need not be the case. Schroedinger’s equation was “just what one was looking for,” but looking as active researchers, not as bureaucrats of so-called knowledge. It answered a definite series of “why’s” that had been asked about the hydrogen atom and “addressed” most of the relevant observational data.

To try to construct metatheories of verification and falsification or confirmation and disconfirmation that would justify a decision to reject or adopt a theory implies a neglect of heuristics as an integral part of the

dynamics of theories. There is no separate cognitive or epistemological dimension such that if it is not reached, the theory should be rejected in research, whatever its merits on heuristic dimensions. And in speaking of the scientific enterprise, it is research, not knowledge, that is crucial.

Karl Popper (1963: 228) and others have worked toward the establishment of a criterion that would enable (genuine) science to be demarcated from pseudoscience.

Psychoanalysis is considered by Popper to be a pseudoscience. But at the Institute of Human Science (Yale), psychoanalysts and behaviorists, inspired by C. L. Hull and others, successfully collaborated in translating some of the ideas of psychoanalysis into a more testable form. There has never been anything definitely “wrong” scientifically with psychoanalysis as a whole, perhaps only some persistent weaknesses. For an excellent survey of the questions, see B. Christiansen (1964). If one wished in all seriousness to disqualify psychoanalysis, one would have to criticize definite published psychoanalytic hypotheses defended in quotable papers, as Popper always does when commenting on physicists’ hypotheses. There must be a fair trial. It is perhaps unnecessary to add that if such a confrontation is made, any clear-cut demarcation formula is apt to break down.⁵

From the point of view of social development and the free society, genuine science seems, through its influence, to be more of a threat than the hundreds of sects that firmly believe in what Popper or Lakatos would call pseudosciences. The sects counteract uniformity and other-directedness and have no chance of establishing thought monopolies. Small-scale irrationality is of little importance compared with the global irrationality created by dominant “scientific” worldviews fostered by “genuine” science. There is a “competitive-selective aspect of a methodology” (Spinner: 1968), but to win is to win in relation to a worldview, not to *any* worldview.

The insistence, in the abstract, of the fallibility of science has increased the prestige of, and confidence in, science, not diminished them. But more than anything else, perhaps, we need courageous proclamations of values that are different from those said to follow from a rational, or even scientific, world outlook.

The enemies of a free society are to be found today in quite other directions than in the 1930s.

According to Popper (1968: 91), “science often errs and . . . pseudo-science may happen to stumble on the truth.” If this happened more and more frequently according to those who were applying Popper’s criterion of pseudoscience, would it never be wise to move the line of demarcation? Surely it would, and the effect of a few moves would be to lower the pretensions of the demarcation so that, for instance, it was used only as a basis for issuing yearly bulletins about what looks most scientific at the moment in relation to theories adopted within specified communities of researchers.

Lakatos continues Popper’s program of elaborating “objective and critical standards of growth” of natural science, especially physics. The aim is in part to advise the scientist and to give him a measure of what is good and what is bad, or at least of what were the good and what were the bad decisions in past research work. If the critical standards are followed, a high rate of growth is to be expected, and if not followed, one can expect a low rate or stagnation. The details of Lakatos’s proposals can only be understood by careful analysis of the “Popperian” approaches within the “logic” of research since 1934.

Here I shall only state some conclusions from the study of Lakatos’s recent papers (Lakatos 1968a, 1970):

1. The criteria of whether a theory *or* a research program or a hypothesis *should* be abandoned (until further notice or finally, in part or in whole, by all or by some) are local in character, both in space and time, and highly tentative. There are no general rules or standards (except very trivial ones).
2. Study of past decisions (concerning abandonment) reveals astonishing, unpredictable revivals (rehabilitations) of theories that were universally abandoned for very good reasons in terms of Lakatos’s own standards.
3. Great scientists have tended to avoid shifts or changes in theories that had little prospect of “producing” new and astonishing facts—sometimes, however, one had to wait very long for such happenings.
4. Proliferation of theories, etc., serves scientific growth, but one should note (temporary) successes and setbacks and abandon them neither too early nor too late.

5. If carefully reconstructed historically, decisions to abandon theories, etc., are on the whole rational. I take Lakatos to mean that there are grounds and reasons for the decisions that we find intellectually understandable and correct.

These conclusions formulated with the use of a minimum of technical terms are important in supporting our pluralist and possibilist views. It should be noted, however, that the aim of Lakatos is not to support or attack such views, but to solve demarcation problems.

The very complexity and tentativeness of Lakatos's normative and descriptive demarcating formula suggest that research policy might be fruitfully studied in a wider frame than that which he adopts.

Research programs in natural science are today perhaps more than ever bound up with technical questions such as: what kind of machinery is available and at what cost? Program *A* is technically so costly that the competing programs *B* and *C* must be given up if *A* is chosen. Or, theory *A* suggests rich possibilities of tests and new facts but is very costly, whereas theory *B* requires practically no apparatus, but (highly tentative) estimates of what will be found are somewhat less optimistic. Further, decisions on research policy affect human values through pollution, degrading use of persons in experiments, etc.

These and other factors strongly influence the *rationality* of research policy. Standards of rationality depend on value priorities, individual and collective. There is no autonomous "scientific" policy.

The intellectual interest of two researchers or two research communities may be systematically different: for the first, high technical and logical achievement is a paramount value; for the second, there is broad interest in the objects of research (for example, climates, fossil animals, and particular classes of numbers). It is *rational* to pursue different research policies in the two communities.

Research as an activity cannot be rationally independent of the rationality of individuals, groups, robots, or communities pursuing research. One may construct an ideal of research inhabiting "the third world" of Popper and Lakatos such that research follows a set of rules—for example, maximizing the rate of growth of scientific results of certain kinds. The *effectiveness* of actual research may then be measured relative to the ideal. But I think one should be careful not to identify rationality of research

with any ideal that takes research as a completely autonomous activity and postulates one particular measure—for example, rate of growth of certain kinds of results. Rationality should be measured, if at all, in relation to maximally wide systems—that is, systematic philosophies.

Research policy may be rational even if “maximization of scientific rate of growth” has a very low priority. Lakatos sees a threat to rationality in Feyerabend’s hedonistic proclamation “Do as a researcher what you wish and have a pleasant time” (Feyerabend 1970a)⁶; but *if made explicit*, requirements of joy in research need not lower rationality, only effectiveness. Continued tests of theory *A* may be found excessively tedious and abandoned mainly for that reason. The shift to other theories may in this case be perfectly rational but it is clearly against an effectiveness-promoting rate of scientific growth. Scientific enterprise may show continuous rationality under variation of effectiveness or continuous effectiveness under variations of rationality.

As described by Lakatos, a researcher, in order to be rational, seems to need unusual intellectual brilliance combined with narrowness of vision and interest. Why can’t a rational researcher be of moderate intellectual ability and pursue his research in the spirit of an amateur or of a man *primarily* devoted to social reform, not to science?

Human interests, passions, and idiosyncracies do not necessarily interfere with the rationality of research. Rationality means primarily rationality of decisions. If a researcher consciously and deliberately chooses a theory in part because testing it necessitates a long-desired journey to the Antarctic, it may reduce effectiveness (for example, speed of growth of research, number of new astonishing facts), but his research as a human activity is more rational than if he chooses the same theory under the illusion that it necessitates a trip to Africa.

At this point it might be clarifying to examine a well-known pronouncement of Willard Quine (1953: 43): “Any statement can be held true come what may, if we make drastic enough adjustments elsewhere in the system.”

As a slogan, a jubilant expression of freedom in theorizing, this sentence has great value even without accompanying explanations. From the point of view of scientific research, however, something should be added: “holding true” does not imply, in research, entertaining a belief as true, but treating it as if true, acting or deciding in a way that would not be dif-

ferent *if* one considered the theory true. Further, it might be added that in research we only make drastic adjustments *for a limited purpose*, and they are all *revocable*. And sometimes we need not bother making adjustments, because “Is it *true*?” is a rare question in evaluating theories.

Looking back at the history of such famous theories as those on acids in chemistry or on light in physics, perhaps much faster progress could have been made if some scientists had not tended either to accept them *as true* or reject them *as false*. A more differentiated strategy, applying “drastic adjustments” in the face of major setbacks from observational disconfirmations, would have kept alive—that is, kept up to date—more *theoretical alternatives*. Such a strategy could have made it much easier to compare the virtues of different theoretical approaches.

Suppose that from a well-established theory we derive the statement that a certain kind of event is physically impossible (for example, that, according to Einstein’s theory of relativity, it is impossible to increase the speed of a material particle from a level under the velocity of light to a level at or above that limit). From a wider perspective we may nevertheless accept it as physically possible—that is, from theories constructed by modifying at least one sentence in an exposition of the original theory without changing the level of observational confirmation and positive relations to other (established) theories. That we can always do this is part of what is asserted by a metatheorem we shall call the Mach-Duhem-Poincaré principle, which is briefly formulated as follows:

Given a set of observational sentences, a set of theoretical sentences incapable of direct observational test, and sets of initial sentences such that the theoretical sentences joined with appropriate parts of the initial sentences permit derivation of the observational sentences, there are indefinitely many other, mutually incompatible, sets of theoretical sentences such that the given set of observational sentences can be derived from them. The expression “there are” may be replaced with “if n sets are available, it is possible in practice to construct a set $(n + 1)$ fulfilling the conditions.” “Incompatible” is used in a wide sense: there is incompatibility if there is at least one observational sentence derivable from the one set that contradicts an observational sentence derivable from the other.

But, it might be objected, there is no *guarantee* that such a variety of *nontrivial* theories can be found. And even if they are, the modified forms may not be acceptable to researchers as ones they could *work with*. These

objections do not hit the mark, because the *possibilities from wider perspectives* do not pretend to be as, or even more, acceptable to the active researcher within his specialized sphere of theoretical activity. The widening of perspective has an importance independent of any such pretension.

Pragmatic-Heuristic Component of Conceptions of Refutation

The picture of the test process given in chapter 2, pages 20–21, seems to indicate that there can be no refutation without the assumption that each member of the set of initial-condition assertions, *I*, can be conclusively *verified* as part of the test procedure. Many of the members normally have the character of conjectures, perhaps refutable, but scarcely verifiable. And what is worse, it is to a large extent arbitrary how many assertions are included in *I*.

The absence of refutations does not harm the development of research, because rejection or acceptance (of working theories and hypotheses) does not depend on refutation. The *justification* of a decision to reject or continue work with a hypothesis is given by answering a long series of questions on its status. The situation as regards instances of observational disconfirmation is only one factor.

The position that there can be no conclusive refutation, however, is misleading. The formulae have been adapted to the contemporary two-valued logic of truth and falsity. But as used by scientists and historians of science, the terms “verify,” “falsify,” “refute,” “establish,” and other terms closely related to the process of testing *theories* have not been narrowly tied down to the true/false distinction of formal logic. Only compelling reasons should make us depart from this kind of usage. The instrumental aspect, the functioning of a theory as a tool in research, has always been a consideration when assessing the weight of a confirmation or disconfirmation, by observation or by theory. Thus the borderline between acceptability and unacceptability, between the status of being established and being not quite established, between conclusive and not conclusive confirmation or disconfirmation, between tenability and untenability, has no definite relation to the distinction between “established as true” or “not established as true.” Here I am tempted to quote Ernest Nagel extensively and approvingly:

The use of theories is one patent factor in reflective inquiry. . . . Reflective inquiry is instituted for the sake of settling a *specific* problem, whether it be practical or theoretical, and inquiry terminates when a resolution of the problem is obtained. The various procedures distinguishable in inquiry (such as observation, operation on subject matter including the manipulation of instrumental symbolic representation of prophetic of subject matter, symbolic transformation and calculation, etc.) are to be viewed as instrumental to its end product. . . . Accordingly, in their actual use in science, theories serve as *instruments* in specific contexts, and in this capacity are to be characterized as good or bad, effective or ineffective, rather than true or false or probable. Those who stress the instrumental function of theories are not necessarily committed to identifying truth with effectiveness and falsity with uselessness. Their major insight does not consist of denying the meaningfulness of certain types of inquiries into the truth of theories but in calling attention to the way theories function and to the safeguards and conditions of their effectiveness. (Nagel 1960: 264–65)

These quotations, taken from Nagel’s “final remarks” in his paper “Probability and Degree of Confirmation,” point to a restrained instrumentalist view that does not commit its advocates to identify “falsity with uselessness” and, I would add, that does not identify rejection of a theory with rejection of a truth or confirmation claim.⁷ Having in mind how theories function within the tremendous complexity of the total research process, it is clear that the introduction of ad hoc auxiliary hypotheses, the ad hoc changing of assumed truth values of some hypotheses (some H_i ’s), or of some statements of initial conditions or of experimental setup (some I_i ’s and E_i ’s), may very well be part of an excellent research policy; such actions need not reflect any diminished attention to intellectual honesty or love of truth. The passage quoted from Nagel becomes misleadingly instrumental only if we ignore his careful wording: “[T]heories serve as *instruments* in specific contexts, and in this capacity . . .” He does not say (or imply) that theories do not serve in other capacities.

Feyerabend has argued convincingly how certain hypotheses that are false and inconsistent—which the scientific community, for good reasons, accepts—may nevertheless function as the nucleus of condensation for new kinds of evidence and the construction of new sets of interrelated hypotheses. Perhaps only after several generations, these hypotheses become corroborated and consistent to a degree comparable to the hypotheses that they supersede.⁸

There is nothing paradoxical about new insights or the building up of a new (or old) theory sufficiently remote in content from the dominant one, starting from a basis that may seem ludicrously slight from the point of view of the dominant theory. The scientist who goes against the dominant trend must *trust* or, if of a cooler temperament, at least “presume ad hoc” the emergence of new kinds of evidence and interrelations. There can be no rational basis for this kind of trust or presumption as judged from internal standards of research. The scientist develops and elaborates a “mere” *possibility*. The rationality, in a narrow sense, of his choices can only be argued in retrospect, if at all. But, as we shall argue later, criteria of rationality may be introduced relative to wide philosophical systems.

It is perhaps the greatest merit of the new historiography that it encourages *both* stubbornness in face of near-universal, rationally argued resistance within the scientific community and the legitimacy of an “orthodoxy” in the sense of continued work with a definite “traditional” theory and practice as long as no alternatives are in the making and in spite of disconfirmations and paradoxes.

The foregoing arguments in favor of stubbornness concern new theories. They should be generalized, however, because in a very vigorous research climate, all theories have the character that we have attributed above only to new theories. When there are no “resting places” for theories because research is carried out in all directions at once, the shortcomings of any theory are revealed more easily and more frequently. There is a continuous stream of evidence and counterevidence. Theories that from a superficial or narrow point of view are “refuted” are, under favorable circumstances, kept up to date, thus making it difficult or impossible for any definitive version of any theory to dominate or enslave the imagination.

Let me once more mention the theory-observation relation in a “competitive market”—that is, in environments with several competing theories. Let $\{O+\}$ symbolize the set of those observational sentences (predictions) derived from theory S that have been tested and given a positive result. (“What was predicted was also found to happen.”) Let $\{O-\}$ symbolize the corresponding set that has given negative results. Let $\{O'+\}$ and $\{O'-\}$ be the corresponding sets related to a second theory S' . Some of the more important relations are as follows:

$$(1) \quad \begin{cases} \{O_+\} \subset \{O'_+\} \\ \{O'_-\} \subset \{O_-\} \end{cases}$$

In this case S and S' are eminently comparable as regards evidential, observational support (corroboration), and S' is unambiguously the better theory, the superior theory *in this respect*.

Nearly all other kinds of cases lack the unambiguity exhibited in (1):

$$(2) \quad \begin{cases} \{O_+\} \subset \{O'_+\} \\ \{O'_-\} \subset \{O'_-\} \end{cases}$$

In this case S' is superior in relation to “strengthening instances,” whereas S is superior in relation to “weakening instances.” Most other cases are even less clear-cut—for example, the cases in which some fields in which the theories have been tested are more or less disparate.

Test of Isolated Hypotheses Practicable

The assessment of the test must take into account the details of the use the scientist makes, or rather proposes to make, of the theory, within his research program (with its policy declaration) in its relation to the situation at the frontier.

Duhem argued that when we say that we test one definite hypothesis, we are really testing a whole theory involving that hypothesis. We might as well add that we then also test *all* auxiliary statements implicitly assumed to be true when making the experiment that is said to test the (isolated) hypothesis. But this may seem rather strange. Do we really test things that we do not know about and assumptions we have never *intended* to test?

There are two distinct problems involved: that of how to test a given (isolated) hypothesis by planned manipulation of certain variables, and that of assessing the possible influence of other variables on the results of the test. If a hypothesis is tested by determining the position of a star image through the use of a telescope, vast fields of optics, physical and physiological, are involved.⁹ The outcome and interpretation of the test *depends on*, and is *influenced by*, all these theories, hypotheses, observations, assumptions, postulates, and so forth. The astronomer must ask: Is the

result of the measurement of the position *unduly* influenced by an imperfection in the telescope—an imperfection perhaps due to a mistake in the fundamental theories of optics used as the basis? Is there something suspicious about the position of the telescope and the vast number of other details of the experimental setup specific for testing this definite hypothesis? Or are things exactly as they used to be? But little is gained by conceiving the astronomer's situation as one in which *he really tests more than he says he tests*. I therefore conclude that a test with an experimental design adequately adapted to the test of an isolated hypothesis *does* test this very hypothesis and nothing else. It does not *test* the other hypotheses of the theory nor the auxiliary hypotheses. But the test may have *repercussions* on the status of these other statements. And the assessment of the quality of the test may change from year to year because of changes in the status of some theories, hypotheses, and so forth, that were relevant to the test.

Incomparability Due to Differences in Conceptual Framework

Let us refer again to Duhem. The agreement of a theory with established laws is, according to Duhem, mainly or wholly a question of derivability. This means that it depends mainly on inventions in mathematics and logic. Revolutionary progress in physics therefore cannot be expected to come from disagreement between a dominant theory and physical laws.

If a theory asserts a definite relation R_1 to hold between a set of variables—for example, mass, core charge, velocity, and so forth—disconfirmations suggest different relations R_2, R_3, \dots between *the same* variables. New laws, or strong disconfirmations of some of the old, may be said *logically to necessitate* some kind of modification of a theory in order to ensure coherence. But they cannot necessitate a change of *theoretical concepts*. Let A, B, C, D be the theoretical concepts in terms of which “established” theoretical laws are formulated. Any theoretical laws *contradicting* the established ones must be *in terms* of the established ones—how could there otherwise be contradiction? Adoption of new theoretical concepts is never forced on us by a negative trend in results of observational tests.

If, now, Duhem's view is taken seriously, changes in theory will only or mainly be dependent on changes in opinion about which theoretical laws are correct. Given certain laws, maximum changes will therefore

remain inside the realm of formulae using the old set of theoretical concepts. But revolutionary change involves new concepts and new ideas, which are *not* definable in terms of the old. It seems therefore that the Duhemian approach does not account for radically new theories.

The basic ideas or conceptual framework of a theory cannot be affected by sets of observations either, since both confirmations *and* *disconfirmations* are *in terms of* that framework. With appropriate changes—that is, modifications of the theory—disconfirmatory instances are changed into confirmatory or irrelevant data—but the conceptual framework is retained intact.

We may even form a kind of principle of *perpetuum immobile*: No theoretical or practical work aiming at testing certain theoretical laws or a definite theory, taken in isolation, can bring forth evidence against the basic conceptual structure of the theory. The worst that can happen to a molecular theory is that it seems that molecules behave very differently from what the theory says—that *they* have quite different properties. But this does not refute the existence of molecules or invalidate the concept “molecule” in the basic structure of the theory. What happened in the case of the instinct theories in psychology before their abandonment was not the refutation of the existence of instincts, but, on the contrary, the excessive proliferation of instincts. In his survey, Luther Bernard (1924) listed 842. (The example is not perfect because most “theories” of instincts do not fulfill reasonable or even minimal conceptual requirements of a theory such as those mentioned in chapter 3 here.)

If two theories are mutually inconsistent, I repeat, they may nevertheless both be confirmed or both disconfirmed by exactly the same set of established theoretical laws. This is due to the circumstance that a theory has more consequences than *just* the set of current accepted laws. But if a new theory has a different conceptual framework from the old, the theoretical laws derivable from the old theory cannot be derived from the new. From a theory in terms of concepts *A, B, C, D*, only laws in terms of *A, B, C, D* can possibly be derived. A law in terms of the concept *E* cannot be derived except when *E* is reducible to *A, B, C, D* or definable by these concepts.

What happens in actual practice, of course, is that the terms of the old theoretical laws are slightly or extensively redefined—mostly without any corresponding change in symbols. Stability in the linguistic apparatus provides an appearance of continuity. The letter *m* and the four letters *mass*

will be retained as long as there are mnemotechnical reasons for retaining them, and those reasons have little to do with meaning- or use-constancy.

Turning now to empirical laws, the same conclusion holds, but perhaps it calls for additional commentary. “Metals expand when heated” contains three key terms used to refer to everyday observables and none of these terms are specific to any competing theories. Two mutually inconsistent or theoretically incomparable theories may therefore both permit the quasi-derivation of “Metals expand when heated.”

I say “quasi” because one needs, in addition to the theories themselves, different sets of “rules of correspondence,” or “*Zuordnungsdefinitionen*” (Reichenbach), that connect the observables with vast theoretical, conceptual frameworks. Because of the one-many relations between the terms of the empirical laws and the theoretical terms, the confirmation of one theory implies neither a disconfirmation of theories contradicting the first nor a disconfirmation of theories with incomparable conceptual frameworks.

Suppose that in the time interval $t_2 - t_1$ a number of natural laws are said to be established and that an accepted theory T_1 (at time t_2) is found to be inconsistent with one or more of the laws. Some would take T_1 to be refuted, others not. The room for genuine disagreements is seen to be considerable since, first, it is not establishable a priori whether T_1 need be in disharmony with any single *observation*, and second, even if it is in disagreement with such an observation, it is not specified whether there are other theories, T_2, T_3, \dots that can take over the functions of T_1 more satisfactorily. If one takes refutation to justify abandonment, both conditions must apply in order to classify the theory as “refuted.”

Let us use an illustration from the calculus of propositions: that q implies r , and p is inconsistent with q , does not exclude that p implies r . The conjunction

$$(q \supset r) \ \& \ \sim (p \ \& \ q) \ \& \ (p \supset r)$$

has the relative strength $s = \frac{4}{8} = 0.500$ —that is, less than the strength of a conjunction of two variables, and far from $s = 1.000$, the relative strength of a contradiction. From the laws (corresponding to a part of q , the rest being *Randbedingung* statements), the observations (in our illustration: r) are derivable, but this does not exclude their also being derivable

from the theory T_1 (in our illustration: p) in spite of the inconsistency of T , with the laws (in our illustration: the inconsistency of p with q). This is essentially the pluralism of derivation on which the principle of Mach-Duhem-Poincaré rests (see p. 37).

Thus, any reported refutation of a theory by natural laws, or by any other theoretical statement “established” by observation, is relative to the outcome of attempts to link the theory to observations *through channels other than the refuting laws*. Now, to relate theories to observations is a crucial task for researchers, and imperfect solutions mean imperfect decidability of the weight of a “refutation.”

In the light of these considerations, it might be deemed surprising that *new* theories are often in vehement conflict with some well-established laws. But if it were expected of a new theory that even in its first version it should not contradict any established law, there would be so few proposals that the theoretical development of science would practically halt. Furthermore, an established law can be deeply modified without losing its admirable relation to observation. Such modification may subsequently bring the law into harmony with the theory.

This may justify a short discussion of a point made by Duhem. He concludes his treatment of testing theories with the dictum that the “only experimental check on a physical theory that is not illogical consists in comparing the *entire system of the physical theory* with the *whole group of experimental laws*, and in judging whether the latter is represented by the former in a satisfactory manner” (Duhem 1962: 200). This might be so if we write “alogical” instead of “illogical.” If laws already formulated in terms of a definite theory are badly represented (I would say badly “accounted for,” “addressed,” or “covered”) by it, it certainly speaks against the theory, but of more decisive importance are comparisons of competing theories in relation to carefully selected experiments. The comparison is alogical in the sense that the conceptual framework by means of which the experiment gets its theoretical import is different for the different theories. When concepts are thus different and mutually untranslatable in practice, the comparison cannot be “logical” insofar as the theories seem to speak of different things. They are not confronted with the same experiment as judged from the sentences expressing the experiment’s theoretical import.

To follow the letter of Duhem’s dictum would be unnaturally to restrict work with theories; designing and testing a theory would become

an exercise in logic and mathematics. What Duhem calls an “experimental” check differs little, if at all, from a logical mathematical check. The relation between law and theory is one of derivability. But if testing a theory is testing this relation, why make experiments? The comparison of two competing theories, and assessment of tests applied to both, call for an assessment of the relation of the theories *to observations*, not just to laws. A theory may be victorious because of its relation to certain crucially important observations—in spite of conflicts with “established laws.” Ernest Rutherford once said retrospectively: “I was perfectly aware when I put forward the theory of the nuclear atom that according to classical theory the electron ought to fall into the nucleus . . .” (Holton and Roller 1958: 624). The conflict was not only with the only competing theory then at hand, but with laws derivable from the theory and based on an immense number of confirmatory instances. Nevertheless, Rutherford’s theory did not conflict with any observations! Nobody had observed whether electrons tend to fall into the nucleus. If laws, as Mach proposed, should be *denkökonomische* condensations of observational data, conflict with laws would be very much more serious than it is. But the relation between the number of observationally established instances of a law and the total number of instances covered by it is as that between a finite and an infinite, or at least indefinitely large, number.

Proliferation of Concepts of Refutation: Pluralism

The historical sources of cases of refutation are texts of various kinds and recorded discussions among scientists. These sometimes end with the rejection of a theory or hypothesis. We are interested in the reasons for rejection, however, and whether they amount to refutations (in various senses) or not. The rejection and abandonment of a theory by a scientist or a community is also more easily inferred from the sources than a refutation. No more use, perhaps, is made of the theory, and the historian asks, “What happened?” He is sure that the theory was rejected and abandoned, but to give the exact reasons is a task of speculation and reconstruction, however rich the sources.

The new historiography has amplified our knowledge of a number of reasons for rejection and consequent abandonment. They are scarcely less

complicated than reasons for social rejection and ostracism. Just as answers like “We don’t like him” or “He’s undesirable” to the question “Why ostracism?” will not satisfy a logician of social relations, the answer “It is falsified or strongly disconfirmed” will not satisfy a logician of science. Logical reconstructions that have any value to research must systematize the reasons, for instance in sets of necessary and sufficient conditions. Such sets will, of course, only approximately, and within limited domains, “cover satisfactorily” the historical sources, but this holds well for any logical construction with descriptive aims. In what follows we have natural science in mind. It is unlikely that a logical reconstruction of processes of theory- (or even hypothesis-) rejection can be disentangled from the special topic (chemical, physiological, sociological, political) to such a degree that it satisfactorily fits *any* theory or *any* hypothesis. At least preliminarily one might have to speak of “rejection in physics since Galileo,” “rejection in experimental psychology,” etc.

The historical sources of the new historiography are overwhelmingly rich and detailed compared with what was available thirty years ago, but there is still a long way to go from these to fruitful conceptual reconstructions of the historical processes. The very richness of the sources makes it psychologically more difficult to make pronouncements on the level of complete generality. And there is even further to go if one wishes to propose methodological norms of rejection.

Our main concern in this essay is not to decide for or against particular conceptions of refutation and refutability, but to point to the room for a *diversity of conceptions*. The procurement of this room is secured by systematic elaboration of the *differences of descriptions by scientists and by historians of particular cases* of falsification, refutation, or rejection. Case histories show great variation and provide the best antidote against prejudices as to what a refutation *ought to be*.

There is a substantial basis for similar pluralism in regard to conceptions of other crucial phenomena relevant to scientific development. This opinion will be discussed in some detail in chapter 4.

From the “economy of thought” approach of Mach, Avenarius, and contemporary pragmatic philosophers of science, rejection is ultimately a question of economics. When it “does not pay” to expend more effort, make more auxiliary hypotheses, or more complications, the theory is rejected.

From the “falsificationist” and “testability” approach of Popper, rejections are conceived more in terms of the true/false distinction and the question of frequency and severity of tests.

But these two examples represent only one major class of dimensions of rejection. We have also the dimensions of consistency, generality, and severity of rejection. A theory may be rejected within one of several domains covered or in all domains. It may be rejected only when very special requirements of exactness of prediction are laid down or, on the contrary, rejected only when a low degree of exactness is required. Further, the theory may be rejected by simple neglect—interest shifting to others until it is so out of date that it is found impracticable to revise it.

Very rarely are the deaths of theories heralded by explicit, careful refutations with well-formulated premises. A theory may simply be talked of less and less, and the predicates used to characterize it become more negative, harsher. Nobody concerned may ever have produced or seen a formal refutation. Thus we have to consider still another dimension: the variety of requirements (or lack of such) concerning *explicitness*. If a theory simply is not heard of anymore (historical sources are silent), is it rejected? What, in short, are the criteria that characterize an *act* of rejection?

It is not our aim here to go into detail, but only to suggest that rational reconstruction of conceptions of rejection and refutation can only proceed fruitfully on a pluralist basis.

Conclusion: The rules and considerations leading up to a verdict, or rather to a decision of “refuted!” or “not refuted!” cannot be isolated from purely heuristic ones. Criteria of truth or falsity and criteria of the goodness of theories have never been as clearly distinguished in practice as they have in discussions of the “logic” of the practice.

The complex relations of actual and potential fields of testing preclude clear-cut decisions as to rejection or acceptance on the basis of observation.

If we are interested in the *logic* of refutation, what kind of symbolic structures should we use? In order to do justice to some of the complexities inherent in the life and death of theories, I think the “logic of indices” might fruitfully be applied. Economists and other social scientists have, for the purpose of condensed comparison, developed indices of, for example, the standard of living, overcrowding, popularity (for example, of

politicians), air pollution, degree of democracy, and many other magnitudes. A great number of factors have to be investigated in order to calculate such mostly quantitative indices, one major concern being the *careful, explicit* formulation of each item or factor relevant to the result. Each researcher might of course propose his own index, but this would defeat the main purpose: to have standard ways of condensed comparison within the research community or within even larger groups. The status of theories in regard to refutation and corroboration may, at some time in the future, be recorded by research teams issuing monthly bulletins that end with index tabulations—neither taken too seriously nor completely neglected by research communities.

III

Theory and Theoretical Idea

Theories: Variety of Notions

The vigor and confusion of the debate on the nature of theories is in no small measure due to the same factor: the vagueness and ambiguity of the term “theory.”

Sometimes the term is used for propositions of any level of preciseness that are not expressions of observations. Thus, Popper (1962: 194) speaks about idealism as the theory that “the world is my dream.” It is, according to him, a false but irrefutable “theory.”

Any assertion of hypothetical character, however vague or trivial, seems to be called a “theory” by Popper and many Popperians (for example, Lakatos). Still others use the term in a very broad way but seem sometimes to require that it contain at least one universal quantifier. If this is the only requirement, one is forced to include the ill-famed “all ravens are black” among our theories and also other primitive generalizations.

Carnap’s concepts of empirical law, theoretical law, and theory provide a better frame of reference. Here the inevitable “all ravens are black” occurs as an empirical law, not as a theory. Empirical laws of temperature are derived from theoretical laws (parts of theories?) by a correspondence rule. “The temperature of the gas corresponds to the mean kinetic energy of molecules” (Carnap 1966: 241). New theories must permit derivation of new empirical laws; those that do not are logically equivalent to the old theories.

Then there are conceptualizations of “theory” that are too narrow for our purposes—for example, those requiring a detailed explicit exposition in the form of a hypothetico-deductive system. The terminology of Duhem is very special, defining physical “theory” as a set of mathematical propositions from which laws can be derived: “What is a physical theory? A group of mathematical propositions whose consequences are to repre-

sent the data of experiment; the validity of a theory is measured by the number of experimental laws it represents and by the degree of precision with which it represents them" (Duhem 1962: 288).

In the last two chapters I deal with complicated sets of fairly precise propositions of various theoretical and observational levels. I need a concept of theory adapted to this purpose. In what follows I therefore take as paradigms of theories in my terminology the wave- and particle-theories of light; the kinetic theory of gases; in chemistry, the theories of acids; and in experimental psychology, Hull's theory of learning, Tolman's sowbug theory of vicarious trial and error (VTE), and Homan's theory of social behavior as exchange.

These complicated structures certainly contain, or *may* be formulated so as to contain, general statements, but there are other features of a theory deserving more notice: (1) *The merely indirect relation to observation*. No observation statement is part of the theory. (2) *The multiplicity of levels*: levels of fundamentals or, better, principles, levels of hypotheses, and laws. (Level of consequences directly testable by observation is not included. It would have to include statements about initial conditions.) (3) *The derivability or quasi-derivability of consequences* and, among them, predictions—observation sentences from fundamental propositions of the theory (when initial statements and so forth are added). (4) *The multiple problem-solving function* (not inherent in "all ravens are black"!), suggesting vast research programs. (5) *The presence of a fairly simple unifying idea* (conception, not only concept) behind the professional (scientific, precise) formulation of the fundamental features.

I have stressed the characteristics most important for the problems dealt with in this book.

I find this general structure, especially point (2), more helpful when studying theories than the one proposed by the many philosophers of science who are mainly inspired by logical analysis. One cannot, without great arbitrariness, take an abstract calculus as one of the three main components of (the formal structure of) a theory. Consequently, it is awkward, too, to make into another component "a set of rules that in effect assign an empirical content to the abstract calculus" (Nagel 1961: 90). This means that we must be doubtful of the significance of the important concepts of *Zuordnungsdefinitionen* and *rules of correspondence* carefully worked out by Carnap, Reichenbach, and others in the 1930s.¹ The main point is that if a

theory is a physical theory, all three levels are physical. There is no “uninterpreted” level. The phrase “a theory may have different interpretations” (Feyerabend and others) is avoided because it suggests that there exist uninterpreted theories or theories not yet interpreted.

Similarly, if a theory is biological, all its levels are biological; none of them are a province of logical or mathematical calculus. Recent work in the philosophy of quantum physics indicates that no exception need be made because of the supposed nonphysical, purely mathematical, instrumental character of the ψ -function and other esoteric symbols.

However important it is for the logician of science to introduce distinctions “so that attention is directed exclusively to the logical relations,” the dynamics of scientific test procedures require very different conceptualizations. The three levels of statements proposed above only provide a model of the formal or linguistic structure of a theory. One must be careful not to *identify* the theory with that structure. If such an identification is made, scientists seem to jump from one theory to another, falsely pretending they are “the same” theories. Or they seem not to recognize clear cases of “refutations.”

The above five characteristics relate mainly to the anatomy or statics of theories. We take our lead from the excellent rule practiced in some countries for defining patents: never give a patent for the *function* of an invention. In defining a lamp for a patent, we must specify its structure (anatomy) and what it is made of, but not how well it lights a room (physiology) or how nice its color is (psychology). But a definition of essentials (*definitio essentialis*) must include functions. In the case of theories, these include the properties brought to light by study of their uses and jobs, of the interaction of one theory with others, and of their place in research activity, programs, policy, strategy, tactics, and in applications that have no research pretensions. All this is relevant to any adequate *essential definition* of a theory, just as the essential definition of an organ of a living animal has to include references not only to anatomy, but also to physiology and acquired abilities. Therefore, I do not take the listed five characteristics to constitute an essential definition.

In order to avoid too much laxity in distinguishing logical, and more generally cognitive, aspects of a theory from the genetic, psychological, sociological, and political aspects, it is convenient to distinguish theorizing from theory. Theorizing is an activity manifested by a theorizer, and it

includes the construction of theories. But the predicates applicable to theorizing are not always predicates applicable to theories. I shall have to go into detail on this theme later when assessing the large-scale attack by continental philosophers of science on what is called *the illusion of pure theory*. Two central questions need clarification: To what extent is this an attack on pure theorizing rather than on pure theory? How “deep” into a conceptual framework within general systems does the distinction between activity and content go?

Whereas the use of the term “theory” and its relations to that of the terms “law,” “hypothesis,” “principle,” and “conceptual framework” show a tendency toward stabilization within the fields of philosophy of physics, in the humanistic disciplines all is still in flux. Reginald Robson (1968: 349) has helpfully distinguished four uses of “theory” in sociology: “theory” as a general name for social ideas and theoretical thinking; theory as social commentary or analysis of social phenomena; theories as taxonomic systems—more or less systematic or comprehensive sets of concepts; and a theory as “a set of interrelated, general propositions that seek to explain empirical uniformities and from which one can deduce further hypotheses for empirical tests.”

Talcott Parsons’s use of “theory” in his influential *Toward a General Theory of Social Action* neatly fits the third of these uses. “His contribution amounts to a ‘conceptual framework’ or ‘frame of reference’ which provides a set of concepts which can be used in describing a vast array of social behaviour” (Robson 1968: 355). Robson formulates conclusions of a team of sociologists evaluating the work of Parsons. I find Robson’s terminology well chosen; the only thing I object to is his tendency to expect fruitful theories to be rather general in scope. Within the vast field of the psychology of learning there are a number of well-defined specific theories, but the general theories are either tautologous or too vague to be of any use—except as conceptual frameworks. Hans Zetterberg’s view of the size of fruitful theories is more realistic (Zetterberg 1965).

Whereas the reading of the great classics of physics will largely be a reading of theories, the reading of the classics in sociology, it seems to me, will largely be a reading of theorizing—especially the wise or acute analysis of social phenomena. Think of Tocqueville, Znaniecki, and others! There are scarcely any theories to pinpoint in the works of these theorists.

Conclusion: The importance of theories for the development of social science is not as great as in natural science. To say “is not as yet as great” would be to reveal some of one’s tendencies in philosophy of science, perhaps a misleading submission of ideals of social science to those of nomothetic natural science.

One more comment on the use of the term *theory* in sociology should be mentioned. Zetterberg writes:

First, there is a habit of designating all the better sociological writings of older vintage as “social theory.” . . . An alternative and better term would be “sociological classics.” . . . A second conception of “social theory” . . . equates it with a commentary on sociological writing, usually from an historical perspective. . . . “Theory” here means essentially “sociological criticism.”
(Zetterberg 1965: 6–8)

Third, there is “theory” in the sense of “taxonomy.” Zetterberg, like Robson, uses Parsons’s frame of conceptual reference as a paradigm. Fourth, there are “systematically organized, lawlike propositions about society that can be supported by evidence” (*ibid.*, p. 22).

Of the many important reasons for reporting these tentative classifications of senses of “theory” in sociology, there is one that has to do with the current interaction between continental and American sociology (and political science). Representatives of the continental trend sometimes take it for granted that the limitation of the term *theory* to both Robson’s and Zetterberg’s fourth sense implies a devaluation or criticism of works falling under the first three classes, or a program of future elimination of those kinds of work. But this elimination is a suicidal approach and is hardly recommended by any contemporary metatheorist of sociology. Both Robson’s and Zetterberg’s fourth sense differ from that of the term *theory* adopted in this work, especially by leaving out the theoretical idea. A set of interrelated propositions without a unifying idea cannot be a theory in my sense, but then the aims of those writers are different from mine. There is no “disagreement.”

The intricate relation between theoretical idea, theory formulation, and observational test can be studied by comparing the achievements of Julius Robert Mayer, James Prescott Joule, and Hermann von Helmholtz in developing the principle of conservation of energy. Mayer “found the new idea,” and the “fame of discovery,” therefore, belongs largely to

him—according to what Helmholtz himself made clear. But *exactly* what idea? Mayer starts from the postulate *causa aequat effectum* and the dictum that energies are causes. He deduces, in the best of metaphysical traditions, that energies are “*indestructible convertible entities*” (Holton and Roller 1962: 351–57)—like all other kinds of causes. *This* is the idea. . . .

It is clear that there is a long way to go from the contemplation and formulation of this idea to a professional statement of a theory in physics. Helmholtz did it—and most elegantly. But the next hundred years of development of conservation principles show that neither Helmholtz’s *formulation*, nor any other, could take over the role of the idea. Every modification and elaboration had to get its inspiration from, and take its cue from, “the” idea—“the” in quotes because there is of course no *definite* idea, but a family of ideas with vague outlines.

To James Joule goes the honor of having invented a suitable experimental setup for testing the theoretical statements. His and other experimental designs are interwoven with ad hoc theoretical assumptions. Just like Mayer, his conviction that the energies *are* conserved had a metaphysical background—and content. He thought it would be “manifestly absurd to suppose that the powers with which God has endowed matter can be destroyed” (ibid.).

The idea of theories mirroring reality, being somehow isomorphic with the structure of how things really are, still plays a considerable role in sociology and political science. The theories of one-dimensional society (Marcuse 1964), of the structure of dominance in highly industrialized Western societies, and of the breakdown of communication (Jürgen Habermas) may be taken either as ideal-typical constructs, which are social science’s functional equivalents of models in natural science, or as mirrors of reality. If the latter, it is easier simply to take them *to be true*, to act on them, and to form political strategies based on them. If we take a social theory to be a construct or a model, however, the way from theory to political practice is more intricate. This is perhaps one of the reasons why the mirroring conception of theory is still not only alive, but growing in importance socially with increasing political activism.

The great historical theories are in a sense more or less permanent crystallizations of certain ideas that represent a quite unusually happy combination of hunches—of fluid, fragmentary ideas constantly cropping up in the intensively active minds of great researchers.

Both the fluidity and the diversity of these fragments can be judged from a recent contribution to the materials of psychology and sociology of discovery — the autobiographical account by James Watson (1968) of the discovery of the three-dimensional structure of DNA. What he and his collaborators were looking for was not a theory, but a “correct hypothesis.” Nevertheless, theoretical ideas in great numbers—most of them, of course, borrowed from others—were cropping up in their minds. Tests were made, mostly with accepted theories and hypotheses, sometimes by confrontation with observational journals, and ideas were dropped—as wrong, misleading, insufficient, etc. The account is excellent as an illustration of *theorizing* and of the complex relations between loose, fragmentary ideas, relatively well-formulated ideas with some clearly worked out consequences, and elaborate, systematic ideas on the way toward adequate expression as a precisely formulated theory.

The differentiation of theories from related phenomena requires a short treatment of the trilogy of theory, working theory, and theoretical research program.

The term *working hypothesis* has long been used for a tentatively, deliberately adopted-until-further-notice hypothesis *during* a research activity. What one does with such a hypothesis is, among other things, to derive its consequences; to compare them with those of other (incompatible) hypotheses; to test predictions (singular statements testable by observation); to investigate which already accepted theories might have the hypothesis as a consequence and which not; and further, to look for experimental setups that might increase testability. These and other activities are normally expected to furnish premises for decisions on whether to rely more heavily on the hypothesis as part of a wider research program or to drop it.

The term *working theory* is used less but can be given a strictly parallel use, except that working with a theory is still more complicated and has more aspects.

The notion of a “working theory” leads naturally to the consideration of research programs and their relation to theories. It is quite customary, as we have already mentioned, to formulate decisive parts of a program in the shape of a theory. “Complexes are really attitudes”: this formula was used by academic behaviorist psychologists to express a program, namely that of systematically reformulating psychoanalytic hypotheses about

complexes in terms of attitudes—that is, behavioristically into patterns of reactions. If successful, the program leads to the establishing of a theory, but at least at the initial stages the theorylike formulations are not expressive of any theory. It is a theory *in spe*, not even a “budding” theory.

The very close relation between the performatory use of theory formulations, namely as expressions of a program, and the more stiffly cognitive use makes it important to map out the differences between the conditions of programs and those of theories. The decision to start, continue, or close a program may be more or less wise, rational, clever, well-founded, or realistic. The refusal to give it up may be more or less stubborn, tenacious, etc., but not dogmatic as in the case of a theory. The designations “true,” “false,” “tenable,” “corroborated,” “confirmed,” “refuted,” etc. do not apply to programs (some of them are misplaced even in the case of theories).

The notion of a research program is used by Lakatos (cf. 1970) to express what I would call “programs of maximal size and of philosophical import.” He uses as a paradigm “the cartesian metaphysics C”: “in all natural processes *there is* a clockwork mechanism regulated by (*a priori*) animating principles” (Lakatos 1968a: 179). Lakatos argues convincingly that it serves the growth of scientific knowledge to stick to such a program even if it is temporarily untestable by basic statements, in Popper’s sense.

Theories: Names, Expositions, Versions, and Modifications

Let me begin with an example. The term “Bohr’s theory of the hydrogen atom” does not, and never did, refer to a definite set of propositions. There is a conceptual scheme, an idea, that in the hands of a genius affected a formidable conceptual breakthrough. The scheme does not permit exact delimitation but is perhaps most easily approached through the theoretical postulates or assumptions by which Bohr was able to derive a vast number of empirical laws summarized by the formula:

$$\frac{I}{\lambda} = R \left(\frac{1}{m^2} - \frac{1}{n^2} \right)$$

Essential aspects of the scheme are the following: The electron can move only along certain orbits, the “permissible” ones. Circulating there, the atom does not radiate anything. This is a famous ad hoc assumption, or, rather, postulate. Testability when accepted: zero. The electron may

drop spontaneously from an orbit of higher energy to one of lower energy. The energy liberated will appear as radiation of a definite frequency. Collisions or radiation directed against the atom make it absorb energy, and its electron *or electrons* are jerked up to an orbit of higher energy. (These are qualitative, not quantitative, conceptions. The success of Bohr's *ideas* was, of course, dependent on the quantitative specifications added to the qualitative conceptions.)

The expression "or electrons" is italicized because it indicates a generalization beyond the realm of the hydrogen atom. The ideas "behind" the professionally formulated theory of the hydrogen atom are such that generalization is psychologically inevitable. In the mind of Bohr, they were probably never narrowly associated with just the hydrogen atom. Such sentences as "the theory was only moderately successful applied to heavier atoms" attest to the broader interpretations: strictly speaking, the theory, as it was professionally formulated, could not possibly, as a pure hydrogen theory, be applied successfully or unsuccessfully to heavier atoms. Among the essential parts of the theory were specific propositions about the *hydrogen* atoms, and to its one and only electron. It would not occur to anyone to simply "apply" these propositions to other atoms. (But they certainly could be applied to ions—for example, the helium atom robbed of one of its electrons.)

Contemplating the high speed of electrons, Sommerfeld theorized in 1915 that relativistic, not classical, mechanics should be used in calculating the orbits. The hydrogen spectra were therefore investigated more accurately to detect deviations. "The results appeared to corroborate Sommerfeld's theory; and at the time, these corroborations were viewed as lending powerful support to Bohr's theory . . ." (D'Abro 1951: 514).

This is instructive because obviously the new spectroscopic findings represented a massive series of disconfirming instances if Bohr's theory was identified with a *definite* version, or even with a definite exposition of a version. That is, the theory should properly have been regarded as "conclusively falsified" if conceived narrowly as identical with any one of the definite professional versions. But in the minds of physicists, the theory was never conceived without its idea or ideas. And the fruitfulness of the ideas was only enhanced by the *modifications of the professional version* necessitated by the consideration of the enormous speed of electrons. In the above quotation there is reference to Sommerfeld's "theory," but in the

history of physics it is plainly a new version of Bohr's theory, in spite of the logical incompatibility of Sommerfeld's formulae with those of Bohr.

After the modification was carried through, deeply affecting the cognitive content of the professional versions of the theory, the new formulations were, of course, still considered to express the old theory, "Bohr's theory of the hydrogen atom." There is a symmetry to be seen here between thing identity and theory identity. As a thinglike entity, the theory is modifiable, has indefinitely many aspects, and is subjected to Leibniz's principle of the inexhaustibility of actuals. But it is the physiology, not the anatomy—the dynamics, not the statics—of the theory that reveals its thing character.

The series of modifications are an open-ended series, as are the forms of experimental setup, which are essentially bound to the theory. New discoveries, by definition nonanticipatable, add new dimensions of possible modifications. Who could anticipate in 1913 the ideas of Sommerfeld, and who could anticipate in 1915 the later idea of the spinning electron? The latter idea introduced what could still be viewed as a modification of "the" Bohr theory, but of course the modifications were now on a scale that made it natural to start talking about an abandonment of "the" Bohr theory in favor of new ones.

Sometimes a name is retained even after the most drastic of changes and expansions. "The quantum theory" was used originally by Max Planck to designate the idea that the emission and the absorption processes in atoms occur discontinuously. In the professional expression of his theoretical idea he specified the quanta as quanta of action. They each have a definite value: $h \approx 6.6 \times 10^{-27}$ erg sec. The professional expression of the theoretical idea was a hypothesis, the quantum hypothesis, in our terminology. It is quite common to look at present-day quantum theory as only a modification and extension of the old "theory"—perhaps similar to the relation between New York City today and New York City in 1800. Example: "The quantum theory has been extended and modified repeatedly since its original formulation by Planck, and even today it is still in a state of rapid change" (D'Abro 1951: 48). Planck himself did not quite recognize or accept the "developments," but he could retain the name "the quantum theory" for what he had himself put forth in 1900.

Our conclusion is only this: if we wish to employ a concept of "theory" that does even minimal justice to the use of the term in present-day

scientific literature, a theory must have a thing character, which both permits different versions of *the same* theory and includes its *idea* as part of the total phenomenon, “the” theory.

If the theoretical ideas behind two theories are clearly different, it is unlikely that the one can embrace the other as a special case, or that the one is “more comprehensive than” the other, taking this relation to be an explicit relation between professionally adequate versions. *Prima facie* there is evidence that those people are right who insist that classical mechanics cannot be shown to be a special case within relativistic mechanics, or quantum physics to be more comprehensive than classical.² One would expect, instead, a relation of incomparability due to basic differences of conceptual structure.

A theory must be capable of being presented by a finite series of fairly precise sentences. But this does not mean that there must be one definite authoritative formulation, “the” (formulation of the) theory. More important, the set of adequate formulations cannot be expected to be logically equivalent—to have identical cognitive content. There must be some similarities, but the extent of the similarity is difficult to quantify.

So far, there have not been two independent researchers who have attributed exactly the same content to Newton’s mechanics. The more important varieties are (logically considered) mutually inconsistent, if not incomparable as regards consistency (due to ambiguities). This presumably holds for the presentations of the Bernoullis, d’Alembert, Lagrange, Hamilton, Jacobi, and Hertz.³

The shortest argument for the indefinite plurality of versions of Newton’s dynamics is perhaps best illustrated by referring to the multiplicity of interpretations of a small part—namely, the laws of motion. Generating differences at this fundamental level means generating different systems of dynamics—systems with different cognitive content.⁴

The formidable complexity of details in Copernicus’s own version of the Copernican theory was not assumed by other versions. “The” theory was always in flux. If by “the Copernican theory” we mean *exactly* the original version, very few ever read or understood it, and it was never believed in, not even by its author. If Newton’s own text of *Philosophiae naturalis principia mathematica* were to be taken as *the* expression of certain Newton theories, they would be eternally infested with dozens of plain errors, mathematical and otherwise.

THEORY AND THEORETICAL IDEA

Referring to the situation of Galileo when defending the heliocentric system, Feyerabend argues:

The advice to *test* his theories would have been quite useless for Galileo, who at any rate was faced by an embarrassing amount of *prima facie* refuting instances, who was unable to *explain* them, for he lacked the necessary knowledge (though not at all the necessary intuitions) and who had therefore to *explain them away* in order to save a valuable hypothesis from premature extinction.
(Feyerabend 1970b: 303)

As reported by Feyerabend, the conflict between theory and observation seems more direct than it would seem when taking the theoretical idea as a genuine part of the theory. Galileo could always move from professional versions of the idea to its qualitative, intuitive core: that the planets move around the sun rather than around the earth. If a theory is completely identified with definite professional versions, as sometimes *seems* to be the case in the accounts by Feyerabend and others, the survival of new theories appears near miraculous and their defenders as heroic and desperate as Vikings fighting on a ship that is sinking or already nearly submerged. I stress “seems” because custom permits us to talk *as if* a theory could be identified with its favorite version, or some of its favorite versions. This custom is reasonable in many ways, but slurs over the not inconsiderable question of how to pick out the approximate boundaries of a theory in relation to a field of ever-growing modifications.

Eddington humorously proposed that since there was so much trouble with entities partly having and partly not having wave or particle properties, a new entity, the wavicle, should be introduced, having just the right combination of both kinds of properties. Why not accept this generous offer? Because whereas the concepts of wave and particle constitute important, very simple commonsense ideas, the wavicle would have to remain a feature of the professional and precise *expositions*. Therefore there are wave theories and particle theories but no wavicle theories! The latter would lack an important ingredient: the theoretical idea.

Among the factors responsible for the semantical diffuseness or vagueness of what a name of a theory expresses, some are very simple, such as the fluid condition of what is taken to be the borderline between the theory as such and a consequence of the theory. When the chain of derivations between fundamentals, or principles, of the theory and partic-

ular laws or hypotheses derived from it is a long one, it is more or less arbitrary which link is taken to be the last of the theory itself and which to be the first within the realm of its consequences.

Further, there are versions with different degrees of generality: "Is it a theory of the hydrogen atom or of hydrogen-*like* atoms or ions?" There are, of course, no standard answers to what constitutes a modification of an old theory and what would be a new theory. How extensively may an Italian Renaissance chair be repaired and still be a Renaissance chair?

From the point of view of formal logic, the slightest change in cognitive content must be said to give rise to a new "theory." And from the same point of view, there may be different expositions but not different versions of one and the same theory.

From the point of view of a historian specializing in long trends, one may speak of "the" wave theory of light as if centuries of theories with different contents are all modifications of one "basic" theory, "the" wave theory. This tends, however, to result in the identification of theory with theoretical idea, a pernicious step in the philosophy of physics. Even in biology it has had awkward results, for example, in untenable assertions on the "anticipations" of Darwin's theory of selection by a host of philosophers. It was Darwin's theoretical idea, not his theory, that was anticipated.

A theory (in our terminology) must be adequately formulatable so as to make derivations practicable. An idea is normally *suggestive* of consequences, but not adapted to rigorous derivations. The formulation and expression of a theoretical idea, while not in itself constituting a theory, is nonetheless a critical prerequisite for theory development.

Behind the seemingly trivial semantical decision on what to designate by "theory" there are nonterminological questions having to do with the "idea" of a theory. Scientists are mostly willing to put their theories into a nutshell, using terms from everyday life and often some pictorial or otherwise metaphorical presentations: "light is waves," "light is particles," "electricity is a fluid," "electricity is an effluvium," "the sun, not the earth, is the center of the universe." Such utterances are sometimes frowned upon professionally but are more apt to reveal important theoretical ideas than are long careful expositions. To consider them "unscientific" may easily result in a kind of castration of the imagination. The following extract from the diary of Darwin illustrates the importance, but also the simplicity of a theoretical idea:

THEORY AND THEORETICAL IDEA

In October 1838 I happened to read for amusement Malthus on Population, and being well prepared to appreciate the struggle for existence which everywhere goes on from long continued observation of the habits of animals and plants, it at once struck me that under these circumstances favourable variations would tend to be preserved, and unfavourable ones to be destroyed. The result of this would be the formation of new species. Here then I had a theory on which to work. (Darwin 1986)

Or in my terminology: “Here then I had a *theoretical idea* by which to work.” And he certainly worked! In contrast to philosophers of previous generations, he worked out a theory and applied it with immense success.

Concluding, then, I propose a separation of the following entities:

1. A *theoretical idea*—vague, suggestive, preferably from the realm of everyday life, intuitive.
2. *Formulations expressing the theoretical idea*. These are vague, ambiguous, “crude,” but superbly fitted for being made more precise, more specific in various directions.⁵
3. *Exposition of a theory*. A definite string of sentences, in professional style, using technical terminology.
4. *Version of a theory*. Several expositions may be logically, mathematically equivalent. They all express one version, one professional *explication or development* of the theoretical idea.
5. *Inequivalent expositions expressing different versions of a theory*. Usual designations: “modifications,” “developments,” “refinements,” “forms.”
6. *The theory itself*—the idea *and* the class of versions.

There is not much to be gained, of course, by adopting this terminology, but it may occasionally clarify issues, especially the relations between logic of science and “science of science”—the many-sided study of the scientific enterprise.

Theory construction and application are part of this enterprise. To understand under what circumstances theories tend to be adopted or rejected requires studying the many aspects of scientific activity—including the climate at the frontier, policies, and research programs.

Some of these points will be elaborated below.

Value and Function of Indefiniteness and Unsurveyability

The understandable longing among social scientists for a somewhat higher degree of clarity and preciseness sometimes drives them toward persuasive definitions of “theory” that we should be happy not to see followed. For example:

A *theory* is a set of propositions complying, ideally, with the following conditions: (1) the propositions must be couched in terms of exactly defined concepts; (2) they must be consistent with one another; (3) they must be such that from them the existing generalizations could be deductively derived; and (4) they must be fruitful—show the way to further observations and generalizations that increase the scope of knowledge (Timasheff 1957: 9).

Brilliant formulations of historically important theories and of the intricate structure of derivations of laws and hypotheses are, of course, the highly valued rewards of lifelong study by philosophers of science, but their results may well create the impression that theories are to be *identified* with hypothetico-deductive systems. Here Michael Polanyi’s warning, well transcribed by Raymond Aron, is apposite:

Only the method of inquiry, of research or of demonstration in fact practised by the creative scientist can reveal the nature of scientific knowledge: its subsequent arrangement in hypothetico-deductive form, whatever its utility, disguises the intention of the knower and consequently the essence of his knowledge. (Aron 1961: 104)

The successful arrangement within a hypothetico-deductive framework is a great and positive achievement, but the essence of knowledge in the sense of the research situation “at the research frontier”—the status of competing theories, of relevant hypotheses and masses of observational journals—is not revealed by a lucid hypothetico-deductive system.

Considering the misunderstanding that when a precise version has been created, the vague but suggestive formulations of the idea are obsolete, archaic, superseded, and therefore scientifically objectionable, it is understandable that scientists sometimes stress the imprecise and undefinable character of important and fruitful “concepts,” meaning what I have here called “theoretical” ideas. Thus, Hendrik Kramers:

THEORY AND THEORETICAL IDEA

My own pet notion is that in the world of human thought generally, and in physical science particularly, the most important and most fruitful concepts are those to which it is impossible to attach a well-defined meaning.⁶

In our terminology: no precise version of a theory exhibits all the potentialities of its idea.

To a theory there belongs an idea. But this does not mean that the *conjunction* of the formulation of the idea and a professional exposition expresses the complete theory. The essential and important vagueness and ambiguity of the formulation of the idea make possible different *directions* in which it can be made precise and testable. The conjunction of the idea-formulation and *one* of the expositions would serve no purpose, and the conjunction of the idea and several elaborations would be inconsistent.

Simple expressions of an idea function as points of departure for strings of sentences with increasing levels of preciseness. Each such string of sentences represents an elaboration in a particular direction.

The importance and also the limitations of “point-of-departure formulations” are clearly seen in the case of the three sentences: “the universe has about the same properties all over except for local irregularities,” “the night is dark,” and “stars are very bright.” From plausible assumptions we can derive the claim that it “ought to be” very bright at night—even infinitely bright. Why is this not so? One suggestion is that it is due to loss in energy of electromagnetic waves originating from very distant nebulae—the Doppler effect.⁷ As soon as we depart from the everyday formulations and survey precisizations in terms of theoretical concepts, the multiplicity of frameworks makes comparison of theories problematic. The observational statements are, just as all others, reformulated into technical jargon. When theories are still considered to be competing theories, theories “about the same subject matter,” and their observational relevance and the status of their agreement with observation are assessed comparatively, it is because the connection with such crude formulations as “the night is dark,” etc. is maintained. Only in this way can there be a common ground and therefore room for agreement and disagreement.

The indefiniteness of content of any interesting theory (due to a multiplicity of versions) makes it impracticable, once and for all, to delimit the class of its consequences or to give any definite rule such that derivable propositions can be separated from nonderivable ones. This immediately rules out the possibility of *surveying* the potentialities of severe tests, falsi-

fication, refutation, and all the other interesting properties. Sampling, not surveying, is a basic need in research.

The usual kind of statement, “Hypothesis H is (strictly) derivable from theory T ,” is substantiated by giving an exposition of (part of) the theory T . If no definite exposition is explicitly or implicitly mentioned, the derivability claim is gratuitous. There is a maximum claim of derivability, “Whatever the exposition and version, H is derivable,” and a minimum claim, “There is at least one exposition of at least one version such that H is derivable.” Considering the diffuse “borders” of the class of versions, the latter claim is rather indefinite. A derivation counts as strict when suitable additions to the premises taken from the theory itself are known or, rather, supposed to be known.

Historically, defenders of competing theories do not agree over what is derivable. An instructive example is the systematic and persistent disagreement between the camps of E. C. Tolman and C. L. Hull during the 1930s over the consequences of each other’s theories of learning. However, it might be argued—with some but not, in my opinion, sufficient justice—that Tolman only had a theoretical idea not a theory, and—with less justice—that Hull lacked a theoretical idea, and therefore also lacked a complete psychological theory. In the case of Lavoisier and the defenders of the phlogiston theories, the old generation did not catch up with the young—they did not have time, energy, and talent enough to answer the criticisms of the Lavoisier crowd. Thus, it came to be said that this and that “cannot be accounted for” by phlogiston, that certain experiments contradicted the theory, etc. This was quite convincing, as criticism is apt to be when derivations from a theory are made not by its users and defenders, but by its fiercest critics. Retrospectively, one must admit, however, that a revival of the phlogiston theory after 1785 would have necessitated the relinquishing of what is arguably the theoretical idea itself, retaining only those basic assumptions that did not imply that something is added to an oxide in processes by which metals are obtained from oxides.

“The supreme value of a new theory is its power to predict new empirical laws” (Carnap 1966: 231).⁸ If we stress the second, and not the first, occurrence of the term *new*—and I think we are justified in doing so—the evaluation of a theory cannot be made once and for all: the derivation of a new law is a *discovery*, with all the unpredictable and astonishing properties of discoveries. Further, successful derivations of new, potential laws

may occur after strong disconfirmations, because derivations often do not depend on the total theory as necessary premises. The weak parts, those responsible for the disconfirmations, need not have been used. Or, even if they have, the new baby is there, whether or not the mother is delinquent.

A theory may revive, blossom, and outstrip another long after it has been declared dead. There is no way of excluding the possibility of a revival—and why should one try? To determine what is beyond the reach of a theory is beyond the reach of a metatheory. This does not imply that it is unjustifiable *to state* that this or that is beyond the reach, say, of classical physics. But care has to be taken not to overestimate in one's assessment of probable life span, evidential or logical support, or importance for research policy. What is said one day to be utterly beyond the reach of a definite theory, may, on the next day, be considered well within its reach. Such changes can be studied anywhere, in any science. A noteworthy example is the existence of what, in cosmology, is called "the red shift."

[It] was first predicted by the earlier studies in the 1920s of the consequences of Einstein's theory of gravitation applied to the universe as a whole. Its discovery was therefore viewed as the most spectacular of the triumphs of that theory, which dominated a couple of decades of cosmological thought. But it was shown very beautifully in 1932 by Milne, McCrea, and McVittre that the "expanding universe" is contained in any effort to describe the cosmological problem in gravitational terms, even using pure Newtonian theory.

(Morrison 1965: 135)

The red shift, if the above is correct, might have been predicted from Newton's theory.

This example illustrates well the inexhaustible character of the class of consequences of a theory. Thanks to the complicated character of derivation, a complete survey is impossible. The most surprising derivations may crop up at any time.

The value of indefiniteness, or the impossibility of attaching a well-defined meaning (Kramers), and vagueness, is not absolute, but is connected with the one-many relation between a theory and versions of a theory. Rigidity destroys the elasticity and rich suggestiveness on which a theory thrives. Moreover, even when crystallized into very precise versions, the class of a theory's consequences is unsurveyable and in constant change because of changes in its auxiliaries.

Value and Function of Indefiniteness and Unsurveyability

The *main* reason for the foregoing reflections concerning notions of theory is not to press any definite terminology on anyone, but to suggest that the variety of opinions marketed as opinions on *theories* are maximally informative only when we take into account the variety of usages of “theory.”

IV

The Unimpressiveness of Impossibilities

Possibility of the Impossible: “Anything Is Possible”

The life of a theory may be long and dramatic: we may speak of its conception, fetal existence, birth, and infantile development; of triumph and defeat; of alternating phases of rejection and acceptance, domination and humiliation, stagnation and senility; and of astonishing rejuvenation and revival. Dark periods of neglect may alternate with stages of excessive popularity. (Seen in this perspective, it is not astonishing that the history of scientific theories now entices so many brilliant students of history!)

Among the well-known revivals is that of Ludwig Boltzmann’s theory of the atom. Boltzmann was regarded as the last pillar of defense of a lost cause, the atomistic-kinetic theory.

Very often scientific progress has been made by a scientist who has revived a theory against all odds, against all plausible and reasonable arguments, in the face of utterly conclusive evidence as judged by legitimate scientific standards.

This is the background of the excellent requirement of Edwin Boring that originality not be measured by absolute newness but by newness in relation to what is generally accepted in the scientific community. Revivals may thus call for more originality than constructing a new theory along the direction of what is already accepted as the most promising one.

There is a fearful contrast between the realistic picture of the exuberant, unpredictable, awe-inspiring life of scientific theorizing and that of a considerable section of the scientific community and the “unenlightened” public. Theirs is a picture reminiscent of the slogan “Grün ist das Leben, grau ist alle Theorie.” There is a tendency to confuse rationality and

THE UNIMPRESSIVENESS OF IMPOSSIBILITIES

understandability with certainty and predictability. "Something *must* be considered impossible, we must know for certain that certain things not only will *never* happen but *cannot* happen." Science is used by the cultured to lift a warning finger to those who let their imagination play with mere possibilities or with what is generally considered to be implausible. But this is a striving for security and results in sleepy conformism. If it is typical of "realism in life," we are tempted to say "Grün ist die Theorie, grau ist das Leben."

Today there is surely no less dogmatism in our scientific communities than at any other time. Or, let us rather pose a question: Who is in a position to judge whether there is more or less dogmatism today?¹ Guessing that there is still some, I feel justified in offering the following slogan: "Whatever the proofs put forth for the impossibility of a kind of happening or process or thing, do not always reject an invitation to inspect an argument for its existence: It *may* exist. *Anything is possible!*"

The word *always* has been inserted because there are, in some fields, so many invitations to inspect ideas that time does not permit serious consideration. In calling "Anything is possible!" a slogan, I do not mean that it is *nothing* but a slogan. It may be taken as an assertion in ontology and made more precise in various directions. Some of them lead to paradoxes or to positions we need not make the effort to defend. Therefore, I find it convenient at this juncture to call "Anything is possible!" simply a slogan.

It has been argued that most scientists, most of the time, would not have worked so hard, and would therefore not have pushed research as far as they have done, unless they had been convinced about the eternal truth and validity of their assumptions, "facts," and postulates, and the unsoundness of any pattern of research different from their own. With certain reservations, this historical generalization seems tenable.

The most important qualification is the following: When a scientist, in his actual work, takes something for granted, without any reservations whatsoever, this does not imply that he holds certain assumptions, principles, or laws to be true or highly confirmed. He is at the moment not concerned with the truth or certainty of *those* propositions. Research practice requires limitation of perspective during each piece of work. This again implies a strong limitation of the philosophical definiteness of intention in application of terms like *true*, *false*, *fact*, *impossible*, *necessary*, or *certain*.²

The above *possibilistic slogan* is not so much directed at the individual scientist engulfed in his extremely limited research program as at the "consumers of science," especially the philosophers and the "educated public," who take their cues from science and are attracted by theories said to be scientific and repelled by those said to be unscientific or not up to date.

To take something for granted—absolutely, and beyond any question—differs vastly when it is done outside a research-problem situation from when it is done inside. The producer of science has a research program in mind; the consumer may have anything in mind *except* just that kind of situation.

The value of the admonition "Anything is possible!" in the face of arguments (in a research situation) for impossibility stems in part from the ambiguous character of the verdict "*x* is unshakeably established." There are so many nonscientific roots of formidable increases in the status of a theory or hypothesis (especially "laws") that it requires exceptional open-mindedness and intellectual power to review the evidence and the chains of derivation dispassionately and with methodological scepticism. The possibilistic slogan requires us to change the question "Is this impossible?" to "Under what kind of (perhaps unlikely) conditions is it likely to happen?"

In daily life and in nonphilosophical writings, there is usually only a difference of stylistic emphasis between "is not" and "cannot be." The extensive use of the latter among natural scientists may have contributed to the belief among philosophers of science that experiments can "show" impossibilities. The eminent scientist John D. Bernal (1967: 25) furnishes us with an example of the philosophically lighthearted use of "could not" and "impossible": "[T]he success of Pasteur's demonstration that spontaneous generation was experimentally impossible. Pasteur had shown that life could not originate except from germs of life already present in the air." Less misleadingly formulated: "In Pasteur's experiments, life 'originated' from germs in the air, and when the air was cleaned of germs, life did not originate. Pasteur rashly concluded: life *cannot* originate except from life."

Some philosophers of science, being great admirers of scientific achievements, are awed by "scientific" proofs of impossibilities. And of course, so-called "postulates of impotency" have had an important beneficial function in certain phases of scientific development. Notable

THE UNIMPRESSIVENESS OF IMPOSSIBILITIES

instances are the “impossibility of transmuting matter chemically” and the “impossibility of obtaining net mechanical energy from a medium by cooling it below the temperature of its surroundings,” and the “impossibility of mass destruction.”

But from the perspective of a historiography covering centuries, the changes in dominant opinion, from “possible” to “utterly impossible” and back, are too frequent and too complex in motivation and justification to be taken as indicative of conclusive discoveries.

In a scientific community—and especially among the young—there are normally traces of hero worship, or at least such a high estimation of certain researchers that when they express a doubt, others are led to doubt, and then to actually find concrete counterarguments. It is very largely a question of authority as to whether a pronouncement of “possible!” or “impossible!” is taken seriously.

Of greater theoretical importance, however, is the scrutiny of *what* is deemed impossible in fruitful postulates of impotency. Let us inspect the postulate “it is impossible to destroy energy.” The principle of constancy of energy has, in the course of a century, revealed its character as a rule (how to calculate) or postulate rather than an assertion. In order to maintain certain invariabilities, specific ways of structuring laws and new “energies” have been put into the equations. That is, there has not been one single theory with a definite energy-constancy theorem as a genuine part. There has been a succession of mutually inconsistent theories that have all been in accordance with a *rule* of energy constancy. Behind the “impossibility” we find a heuristic rule. The impossible is what is *ruled* out. No physical process is declared impossible by the principle of constancy of energy.

The slogan “Anything is possible!” has been related to negations of possibility derived (logically, or otherwise in case of impossibility of phenomena) from theories. But as can be expected from a good slogan, it cannot be rendered in plain informative language without loss. This was already hinted at earlier. If we do so, we get into trouble at once. In analogy with the shift of consideration from “*x* is impossible” to “‘*x* is impossible’ is (only) asserted,” there must be a shift of consideration from “*x* is possible” to “‘*x* is possible’ is (only) asserted.” From there on, we may, once more inspired by astonishing events in the history of science, feel inclined to introduce the slogan “all eventualities except one are impossible,”

stressing that there is only one unrepeatable course of events, or better, "anything may be impossible." After all, there have been completely unforeseen, conceptually confusing instances of phenomena declared to exist or at least to be possible that have later been taken to be impossible—even "proved" to be impossible. So, there is no guarantee that anything that is *defined within a definite conceptual framework* will persist in being taken to exist or even to be possible. But such an "impossibilism" has at the present time—as far as I can judge—no mission. What is lacking in many environments is the clear realization of how little weight a proof of impossibility has if our perspective covers several decades and encompasses the premises and rules of inference used in the proof.

The relation of a pronouncement of "possible!" to definite conceptual frameworks is essential because if such pronouncements are made in a conceptually uncommitted way, they acquire a function different from that within research. Thus, if in an everyday setting I seriously think it *possible* that my horse will win the derby next year running backwards, I am simply wrong. On the other hand, some strange feats of locomotion may well be declared possible in a biological discussion in which the consequences of some new theories are being considered.³

It has been remarked by David Hume and many distinguished contemporaries that a speculative man may hold sceptical doctrines in the abstract that he does not even try to follow in real life. But the converse possibility also needs remarking, that speculative minds may hold dogmatic views in the abstract that do not correspond to their more sceptical ways in real life. An example may make this clearer.

"No physicist would dream of trying to settle experimentally someone's claim to have constructed a *perpetuum mobile*." This I suppose is *wrong*, but wrong as sociology of knowledge and as psychology. That absolutely no such claim would induce a physicist to inspect the construction of a *perpetuum mobile* shows a *theoretical* inclination toward just the same lack of research-mindedness as was shown by those who once refused an invitation to settle experimentally whether there could be movement in heaven or not. But experience shows that at least some, if not the majority, of physicists *are* sometimes willing to join forces in experimentation based on a negation of generally accepted "impossibility." They can be persuaded to do this in spite of the nagging question "But isn't this completely absurd?" It was once agreed that movement (in a certain sense) in

heaven was *impossible*, and how could an impossibility in principle be overruled by experience? The answer is that anyone who is free in his abstract theorizing can conceive an “impossibility in principle” from the outside—as an *asserted* impossibility, a claim, and therefore perhaps merely an error of judgment. With even a little stretch of the imagination, definite sources of error can be conceived, and with still less stretching, definite *kinds* of sources. The situation is then seen in a new perspective. Change of perspective saves us from many dogmas.

One might object that a case of *perpetuum mobile* cannot be settled *purely* experimentally: there is a successful theory from which the impossibility follows. A rival theory would have first to be created from which either the impossibility does not *follow*, or from which the possibility follows (that is, by being clearly compatible). This objection, however, has in part to do with credibility or acceptability as part of a working program. Together with a (seemingly competent) theory at hand, it still makes sense to inspect an experiment that is said to “show” something impossible (according to the only well-elaborated theory available).

But granted that one might be willing to inspect such an experiment rationally without having been confronted with a theory, the objection could still be made that as the *perpetuum mobile* would have to go on forever, no human experiment could convince a man who believes in mortality that the matter could be *settled*. This, however, would be a clear case of interpreting the settling of “empirical” research questions in the sense of definitive verification. The conditions required for justifying the verdict of “settled!” are not of this kind. They contain a pragmatic component and involve a *decision* to stop further inquiry when prospects for obtaining evidence that could unsettle a tentative, ad hoc conclusion are dim.

Today we shake our heads. How could people believe in the conclusiveness of the proofs of immobility in the heavens! We laugh at their expense. And we add, perhaps, that of course *any proof of impossibility starts from premises and uses rules at least one of which is nonevident*. What is easily forgotten, however, is that this mood of openness is apt to vanish as soon as the historical perspective is replaced by the systematical and contemporary.

The term *physical necessity* is often used in regard to well-established physical laws. Any process inconsistent with what is well established is accordingly called physically impossible. The necessity

talked about here is not logical necessity, but deducibility from a dominant theory. However persuasive the theory may be, human creative imagination conceives other possibilities, and sometimes they materialize. That is, after some time a new theory, inconsistent with the old, well-established one, becomes in its turn well established. The old "laws of nature" are reformulated in the new jargon, or sometimes given up. Thus, only by equivocation are so-called physical impossibilities taken to be permanent obstacles. If a creative chemist—to take an interesting example, Linus Pauling—publishes a statement that flatly contradicts extremely well-established laws, the possibility of discarding or modifying those laws is seriously contemplated. I refer to the account by J. D. Watson, who competed with Pauling in constructing a model of DNA. A manuscript by the latter, outlining a solution, fell into the hands of the former, but it contained some highly "unorthodox" chemistry. Says Watson (Watson 1968: 161), "We could not but initially worry whether Linus' model followed from a revolutionary re-evaluation of the acid-base properties of very large molecules. The tone of the manuscript, however, argued against any such advance in chemical theory." (Watson's ultimate conclusion: Pauling had committed a mistake that would have stamped a student as "unfit to benefit from Cal Tech's chemistry faculty.") Either revolutionary advance or crass blunder! These are the alternatives often considered. Of "impossibility," little is said in actual research.

According to Popper (1961: 430), "there may be structurally different worlds—worlds with different natural laws." His view is fully consistent with "possibilism": "Natural necessity or impossibility"—a somewhat wider concept than physical necessity or impossibility—"is like musical necessity or impossibility," imposing "structural principles." It is like the impossibility "of a four-beat rhythm in a classical minuet, or the impossibility of ending it on a diminished seventh or some other dissonance." The main point in my argumentation is that it is still, and is likely to remain, an open question whether "the world," if considered as a musical creation, is a classical minuet, or a minuet of any kind whatsoever. Natural necessity or impossibility imposes structural principles "upon the world" (*ibid.*), but leaves "a great deal of freedom to the more contingent singular facts—the initial conditions" (*ibid.*). But hypotheses of the kind "*x* is a case of natural impossibility (or necessity)" have no function in research except as ad hoc rules and do not restrict freedom in any way

whatsoever. In the terminology of Wittgenstein: science is a game in which we change the rules as we go along.

According to Norwood Hanson (Hanson 1958: 117), “perpetual motion machines and velocities greater than light are not psychologically inconceivable: they are impossible in principle.” It is because of this impossibility that no physicist, according to Hanson, would even remotely consider undertaking an experimental settlement of a claim to have constructed a *perpetuum mobile*.

Here I think a fundamental attitude toward research is involved. From certain exceptionally well-established theories in thermodynamics, one can derive, perhaps even deduce in a fairly strict sense, certain sentences that imply the impossibility of perpetual motions of certain kinds. But what follows? That a theory is ever so well established does not mean that it is established as true. Acceptance of a theory (to work with) does not imply acceptance of it as true or even probable. Therefore, if the negation of a sentence is derived by logic from the theory, this does not mean that the negation is true, or even probable. And if the negation can be interpreted to imply the impossibility of a phenomenon *P*, the sentence “*P* is impossible” does not mean the same as “it is true that *P* is impossible” but rather “it is true that *P* is impossible if the theory is true.” Since the theory is not asserted *as true*, it cannot be derived that *P* truly is impossible.

As John Austin and Ludwig Wittgenstein (and others before them) have tried to teach us, there are many ways of using language, and I take it that the use of language to formulate theories is only one, and a different use from formulating particular truths.⁴ Theories are formed as “normal” indicative sentences, but if *S* is such a sentence, there is, I am glad to say, no exclusive use such that *S* must be taken in this simple affirmative use.⁵ Saying *S* assertively is only one way of saying *S*. But even if the indicative mood were uniformly used in such a way that *S* expresses that *S* is simply true, historiography tends to make us attribute only provisional truth-values to the postulation of impossibilities derived from theories.

Let us inspect an assertion that seems to imply a limitation of possibilities (that is, increase in strength of assertion): “A law sentence expresses an a priori proposition when its user maintains it in the face of all experience” (Hanson 1958: 114). “Confrontation with *all* experience” is

an interesting formula, but how is it applied? Can it be used as a criterion? A physicist may be said to use a law sentence at times t_1, t_2, \dots, t_n . Then he leaves physics, enjoying his pension or simply dying. There is a limit to the number of occurrences our theories about *his* use of the sentence can cover. Suppose we have used modern equipment with tape recorders, television, neurological devices, and interviewers in order to get the richest possible observational basis for our theories. One hypothesis might be, "Whatever this man will experience in his life as a researcher, he will maintain this law sentence." It is clearly an interesting biographical hypothesis, and, if made more precise, only understandable in terms of a comprehensive conceptual system. The conceptions of x *maintains* y are many, and the relation of observations of x and y to the conclusion x *maintains* y is a very complicated one. There are also interesting differences in conceptions of experience and of "sentence." Some would say that we must be fairly clear about whether we are doing research on a formula or on the law that the scientist holds to be expressed by the formula. In any case, a metascientific hypothesis such as " x maintains y in the face of all experience" is unable to furnish any *definite* criterion of "a priori." For example, it can be interpreted as expressing obviously too weak a criterion: "A sentence S is a priori in relation to experiences of class E if and only if S is left unchanged in the face of each element of E ." This criterion is too weak because S might be a priori in relation to most small classes and a posteriori to many rich classes. And again, an obviously inapplicable criterion is obtained if the class is open and therefore potentially infinite. "A sentence S is a priori if left unchanged by users of S in the face of any experience in the past, present, and future." If, after some time, there are no more users of S , a stipulation must be made as to how to conceive the sentence.

It is a valuable feature of Hanson's account of $F = ma$ that he stresses the multiplicity of its functions or uses, and also that he would criticize any concepts of meaning that made use irrelevant to meaning, but I do not see the full realization of the methodological issues involved. If $F = ma$ has at least five main uses, a sentence such as " $F = ma$ has at least five main uses" should not be expected to have less. Nor should we expect that two presumably competent observers and metascientific theorists would class a given instance of the use of $F = ma$ in the same category nor that they would agree on a definite classification of uses. Work done in lexi-

cography and in empirical semantics strongly suggests that there will be a multiplicity of interpretations and different, normally incomparable conceptual frames of reference. What I suggest is that the valuable insistence on plurality of uses must not be limited to *physical* research. It is just as pertinent in lexicographical and empirical semantical research. This has the consequence that argumentation in favor of pluralism is as relevant in those “soft” fields as in the “hard” field of physics.

“The logical point is that some laws *are* maintained in the face of all experience.” Considering scientific development as a process in time and the scientists as actors, the new historiography cannot admit “facts” of this kind. Experience is inexhaustible and no scientists face all experience. If the scientist says, “It is my deadly serious intention to maintain the law to the very last breath of my life,” this is of course an interesting (and astonishingly “unscientific”) statement, but not a sufficient basis for asserting the truth of the claim that the law *is* maintained in the face of all experience. Suppose the scientist adds, “You see, potentially falsifying evidence would be inconsistent with a conservation principle, and, furthermore, the idea of potentially falsifying evidence is psychologically inconceivable.” According to Hanson, he may maintain the law *because of* such considerations (= such hypotheses?). But what if, in the face of some experiences, he appeals to opposite considerations? Hanson himself reveals a potential complication:

Popes die and Commissars are liquidated, the successors may be of opposite opinion: A man might hold to a law against all counter-experience because, for instance, a Pope or a Commissar instructed him to do so. We deplore his reasons, but the logical issue remains unaffected: he uses the law sentence concerned in an *a priori* manner. (Hanson 1958: 115)

So, if the pious scientist outlives n popes who all give different instructions concerning the acceptability of propositions p, q, r, \dots does he nevertheless “use p, q, r, \dots in an *a priori* manner” at every turn of events? For our present discussion, it suffices to conclude that if the actual (factual) obedience to an instruction is made relevant for the question whether a formula expresses an *a priori* proposition or not, there will be room for many conceptions of “*a priori* proposition” and its relation to “use of a sentence in an *a priori* manner.” They will be dependent on contemporary conceptual frameworks in social psychology.

Investigation of the occurrences of certain terms and sentences, applying the available methods and techniques of linguists and social scientists (including historians), discloses the complicated and indirect relations between observational journals covering the occurrences on the one hand and hypotheses about use, function, meaning, import of the terms, and sentences on the other. If investigations could be carried out today as adequately as analogous investigations of occurrences of falling bodies and electric sparks, my guess is that one would find both the relation of theories to hypotheses and the relation of theories to observation to be just as indirect as in mechanics and theory of electricity. *There is no less room for pluralism in metascience than in science.* Metascience is in this, as in so many other respects, nothing more than a part of science.

The difference between acceptance and acceptance as true is apt to influence behavior. A physicist may accept the theory of relativity and accept as logically correct the derivation of sentences implying the impossibility of velocities (of matter) greater than that of light, but if there is a rumor of theories being worked out that do not deny supervelocities, or of experiments that might even show the existence of such velocities—well, wonderful! Nothing makes him more curious than the possibility of “seeing” something violate his fundamental scientific assumptions. There is joy in transcendental stupefaction! One must be prepared for what cannot be anticipated!

This point has to do with the strangeness of the relation between theory and practice. Think of a professor of physics just completing, before an audience of graduate students, the proof of the impossibility of velocities greater than light. A colleague and friend rushes in and tells him about an experimental setup just being tried out that indicates the presence of particles with a speed greater than that of light. “Incredible! Impossible! I don’t believe it!” the professor shouts, but adds *without changing his opinion on anything*: “Let me have a look! Perhaps it is *not* a hoax! The class is dismissed! Let us see what is happening at the other end of campus!” And so they rush off to expose themselves to an impetus that *may*—though it is statistically unlikely—change their attitude. (More likely, of course, the rumor of supervelocities would stem from the announcement of *a new theory* with new consequences concerning velocities.)

Any sociological or psychological model of the rationality of scientists that would rule out this open-mindedness of a physicist toward the

THE UNIMPRESSIVENESS OF IMPOSSIBILITIES

“impossible,” is not only wrong but pernicious. “Anything may happen!” Whatever the articulations in the way of proofs, semantical, mathematical, or logical, they cannot rationally determine their own weight.

Man is capable of reflection, and of reflection about reflection. This makes it always possible for him to go from the n th to the $(n + 1)$ th level. When he has just completed a proof and accepted its conclusion as inevitable, an incident may make him ask “Does it hold?” And even if it holds, has it any bearing on any phenomena? Or, if he persists in being completely convinced, he can make his state of mind an object of research; he can move from living *in* the certainty to living *in* the reflection *about* the certainty, thus making way for the thought that there is a difference between the provenness of the theorem and the state of mind of being completely convinced of its provenness. This again makes a dialogue possible with one who rejects the provenness and makes it possible to work with the assumption that it is not proven. The awareness of this makes it natural to utter “anything is possible,” *angelikos*, in the manner of the Pyrrhonian sceptics.

It is not only basic views of rationality (read: pedantry) that are used to oppose open-minded recognition of possibilities, but also some of irrationality: Scientists, it is said, *belong* to traditions, societies, communities, and ways of life inside which certain possibilities simply *cannot* be seen. People *must* believe in certain presuppositions essential to their tradition. But however fruitful the constructs “tradition,” “society,” “community,” and “ways of life” may be, they should not be taken too seriously. Geyl, Sorokin, Popper, Gellner, and others have successfully opposed the social determinism of Spengler and contemporary philosophers. Within certain sections of the populace, definite views may *dominate* for shorter or longer periods of time, but where one has had the opportunity to make detailed studies, instances of contrary views are found, and no psychological or social determinism has been able to show that those following the mainstream of opinion are completely impregnable to views that go against the dominant ones.

In short, the acceptance at time t_1 of this or that as impossible does not exclude rational openness toward an argumentation for the existence of the so-called impossible at some future time, t_n .

The acceptance of the possibilist slogan may often have little influence on behavior, or more generally, on *praxis*. Comparing the pairs of con-

clusions: "x is necessary" / "x is extremely likely to be the case" and "x is extremely unlikely to be the case" / "x is impossible," there are no consistent differences of weight within the pairs when it comes to questions of research policy. Accepting the slogan means primarily that, under special circumstances, one *uses* as an assumption in actual research, *works out* consequences of, *plans* tests for, and *presumes* the existence of what is generally taken to be nonexistent and incapable of existence.

"But *ultimately* don't we strive as researchers for *knowledge*?" Why this high evaluation of knowledge? There is no clear argumentation that brings us from statements like "according to the now generally accepted theories, x is the case" to "it is known that x." On the whole the stress on knowledge has degenerated into a stress on certainty, permanence, dogmatism, and pedantry.⁶ That research is ultimately motivated by a need for certainty is a dogma that has recently been undermined successfully (for example, by James, Popper, Polanyi, and Feyerabend). This cannot but affect the status of knowledge as a kind of resting place, which is contrary to the whole idea of unending, expanding research.

Research may be motivated by a need to systematically explore intensively exciting and illuminating possibilities whatever the chances of finding evidence that will eliminate the speculative character of the hypotheses. Let us say a researcher works with propositions with four very different levels of "certainty" or of "plausibility." There is nothing in research methodology or a "psychology and logic of research" that indicates that working with only the highest level must be the most satisfactory from some or all points of view.

An example: From time to time rumors reached the Copenhagen circle (Bohr and associates) in the 1920s that a really devastating argument had been found somewhere against quantum mechanics. Bohr and his many outstandingly talented collaborators would then hastily get together and in an atmosphere of almost diabolical fervor try out the strongest possible versions of the argument suggested by the rumor. There was the kind of rush to refute their own theory that would have delighted, perhaps even astonished, Popper.

There was not the slightest doubt, however, that if the rumor were true, and some really fundamental, but until now *completely unsuspected*, weakness were found, this would only temporarily halt the progress of physics. There was also probably little doubt that they themselves, the very creators of quantum mechanics, would be able to participate in new

THE UNIMPRESSIVENESS OF IMPOSSIBILITIES

theory construction; there was probably a pervasive belief that *they* would *be able* to reconsider *everything*. In short, the intensive work that went on on the basis of an acceptance of quantum mechanics did not undermine the disposition to listen to and to study any qualified suggestion implying the rejection of the most basic assumptions underlying their work. The most impossible might turn out to be possible, and the unimaginable imaginable. The open recognition of this was made easy by the well-founded self-respect and the realistic assessment of the capacities of the group's members. Where there is a feeling of impotency, such openness is, of course, more difficult. But in no case is it necessary to accept an ideology of the finality of results.

A study of history suggests that, statistically, this openness is exceptional, but the statistics of attitudes is not the only relevant discipline in assessing what acceptance of a theory means to a researcher in times of the maximum employment of his talents.

Feyerabend stresses that the elaboration of a new cosmology requires a step back from the available evidence—the new cosmology may well start with zero or negative *observational* support. One must therefore not ask of an idea—the nucleus of the emerging new cosmology—that it show its credentials *before* being elaborated in various directions. When an established “impossibility” is rejected, it may still be much too early to ask for *how* it is possible. A theory may tentatively be accepted that makes room for a *perpetuum mobile* without any idea of *what* a *perpetuum mobile* would look like, or *how* it would be possible.

So-Called Completeness and Maturity as Signs of Abandonment

Philosophers who argued against Einstein in the 1920s used a kind of “ordinary imagination” argument to block efforts to overcome the limitations of one's theoretical imagination, treating it as a static factor and not a capacity like that of calculation, which can, and sometimes must, be developed far beyond its temporary limits. There are no *preliminary* checks to an idea; ideas in research are themselves preliminary. Therefore the competition among ideas is always completely open. If a scientist is capable of elaborating an obscure but simple idea in such a way as to elevate it to a scientific level of preciseness and testability, so much the better—the

more independent ideas there are, the more starting points for renewal and decisive progress. The bottleneck is, of course, our limited capacities and eagerness for concentrated tenacious effort.

“Any idea can become plausible and receive partial support,” according to Feyerabend. When an idea becomes “the starting point of concentrated effort,” it is connected with preexisting observational journals and expressions of natural laws. *Using* the idea includes reformulating the law formulations and interpreting the observation sentences in terms of the idea. Obviously, these reformulations can hardly avoid giving the idea substantial evidential support. It is a birthday gift to any clever idea. But only future elaboration will show whether the effort of restructuring is worthwhile. The “good” idea flourishes, the “bad” one is given up, perhaps only after considerable efforts that, unfortunately, are left unmentioned in the historical accounts of scientific development. More should be done by editors of journals to elicit reports on laborious research that, despite adequate equipment, has been unsuccessful.

Considering the chances of a theory’s revival, one must bear in mind that its idea is an already “elaborate” one, and that the competing definite precise formulations along the axes or directions of precization are different in content and that the conjunction of the professional versions is therefore contradictory and, of course, not expressive of the idea “itself.” Suppose we were today to revive “the” phlogiston theory, a most “unthinkable” and thankless job. If we took the professional versions from 1785 and later years as a starting point, we would have to make more and stranger ad hoc assumptions than if we took up the theory at an earlier stage, before it had been elaborated in detail. Revivals are revivals of ideas, and fragments of ideas, not of definite hypotheses expressed in an “ossified” technical jargon.

Feyerabend’s statement that “any idea can become plausible” is closely akin to our more general “Anything is possible!” It has an important relation to our wide conception of auxiliary propositions:

Not being prophets we must also admit that *any* inadequate view, however often refuted and however implausible, is capable of becoming the crystallization point of a new world picture which, taken in conjunction with a new (and perhaps utopian) theory of knowledge, might in the end prove more effective than the most attractive and most highly corroborated element of the *status quo* (no method can guarantee an approach to “truth”).

(Feyerabend 1970a)

THE UNIMPRESSIVENESS OF IMPOSSIBILITIES

A good slogan can be overworked, and this holds true for “Anything is possible!” Suppose we agree that an event that is impossible according to generally accepted contemporary physical theory is nevertheless possible, or even probable or necessary, according to theories that negate some of the untested or incompletely tested assumptions of these theories. And suppose further that we take it as likely that within the time interval of a few generations, such theories, or theories more widely different from our present ones, will be generally accepted. This perspective is rarely, if ever, relevant in the research work of the vast majority of theorists today. As already mentioned, there is a bottleneck: our limited capacities. A super-human intelligence might well point to certain data, laws, or already known events that foreshadow the next major change in physical theory, but what relevance has this for us? Ernst Mach’s lonely opposition to what was generally accepted could be used by Einstein to create something revolutionarily new, and Einstein himself thought that Mach might have come up with the theory of general relativity if external circumstances had been somewhat different. But where are the Einsteins today, and how can they know they are Einsteins? Questions and considerations such as these strongly suggest that if a researcher is tempted to work from premises, which, in part, negate generally accepted physical theories, the slogan “Anything is possible!” should *not* be used to cheer him up: it is *unlikely* that he will get anywhere. Statistically, the chances of eliciting a new “revolution” are small, and the users of the possibilistic slogan ought not to take upon themselves the responsibility of backing up unrealistic revolutionaries just for the fun of it.

Even if we discard certain crude ideas about scientific development as the accumulation of facts, or tested approximations to truth, we may acknowledge an accumulation of documents and other artifacts of scientific activity. This implies a steadily more comprehensive job of obtaining coherent pictures, and noncontradictory, content-rich theories covering the various loosely connected “ $(n + \chi)$ -dimensional” fields of research. The n stands for uncontroversial dimensions acknowledged in the research communities at a definite time, the χ stands for the new dimensions cropping up in contemporary research not yet digested by, or not yet discussed extensively in, the communities.

In rejecting the image of broad theories being abandoned by simple falsification, or new ones being adopted by more complete verification or

confirmation, we are on the verge of adopting a coherence view of scientific “truth” or “acceptability.” The theory that can “account” for more than any other available theory is to be adopted, “accounting for” meaning “bringing into coherent, at least noncontradictory, intelligible connection.”

But even to require no known contradictions as a necessary condition for acceptability is too strong a requirement in view of the dynamics of theory change. For new theories under construction may, of course, contain contradictions—that is, internal inconsistencies—and nevertheless be perfectly *acceptable*—that is, more worthwhile to work with than any other available candidate. Internal contradictions falsify but do not make unacceptable. Contradictions may be present at any level and between any levels—within the basic formulations (the principles), between the basic formulations and some laws or hypotheses considered to be derivable, between hypotheses, and between hypotheses and observation. Further, there may be inconsistency between the auxiliary assumptions and the science from which they are borrowed. Physicists have often worked with clearly inadequate, sometimes squarely false or absurd, mathematical theorems; assumptions concerning observability have been in conflict with psychophysical experimental evidence and so forth. In general, the worker in one science tends to use obsolete data and hypotheses from other fields and often acknowledges his inability to keep up to date. He *should* be up to date, but he often does well enough without being so.

Conclusion: Even if “coherence” is taken as an important *desideratum*, absence of it does not imply unacceptability of a new or an old theory. “Acceptable” in research is not synonymous with “acceptance as true.”

As regards theories that are no longer under construction—*mature theories, completed theories*—they do not “live” under the most favorable research conditions. The belief in completeness reveals loss of interest in expansion and development, both of idea and of professional versions, or reduction of the use of the theory to mere applications. Thus, the “abnormal” character of theory change is due to the perhaps inescapable situation that most theories, most of the time, are applied, not *accepted* in the sense of “accepted as a set of working hypotheses in efforts at expansion.”

The question of definitive completeness raises the recently discussed question of “permanent revolution in science.” Let us make some distinctions: A change from theory *A* to theory *B* may be called revolutionary

only if there is a conceptual incomparability between *A* and *B*—due to profound changes in conceptual framework or practice. As long as *A* can be translated into *B*, and vice versa, there is a continuity that one might consider evolutionary, not revolutionary.

Using this concept of revolution, it is difficult to see on what grounds any revolution should be considered to be a final revolution, however long human beings occupy themselves with science. The main obstacle to finality might be revolutions in society at large. These are likely to affect the practice of science in subtle ways that are resistant to articulation (even if in principle expressible). With sufficient changes, old theories will cease to be understood or be understood in ways too different to make it reasonable to maintain that the old theories are still accepted.

The supposed infinite complexity of nature (and man) does not itself preclude a halt to scientific revolutions. Here I agree with William Kneale (1968: 38). But as regards the possibility of a future, conclusive, complete, and comprehensive theory, I do not see what could reasonably be meant by that. Or, for that matter, by completeness of a science, even if defined soberly as follows: “A science is complete when it gives as much descriptive detail as is desired for the domain of the science and when the theoretical structure of the science satisfactorily explains all the facts of the science” (Schlegel 1967: 46). If, in a new science, there are only two facts and only one researcher with weak desires, completeness seems easily reached! Desires are fragile criteria.

A theory might be termed complete in terms of a definite frame of reference and definite aims of inquiry. Thus, there is a “complete” theory of crystals in the sense that there is a generally accepted theory of all the “possible” 230 forms of crystals. But frames change, as do judgments about possibilities, and there are indefinitely many properties of crystals, not all of them covered by any theory. And it is a wide step in generalization to move from a kind of temporal, aim-related, and therefore highly relative assessment of the completeness of a theory to that of a whole science. I see no point in introducing concepts to characterize the completeness of a science.

The Inexhaustiveness of Ideas: A Semantical Model

The relation between a vague and ambiguous but suggestive theoretical idea and a precise exposition may be schematically presented semantically as a movement from a vague and ambiguous but suggestive *formulation*

(“light is waves,” “electricity is a fluid”) to less and less vague and ambiguous formulations along a definite direction, a direction of increased preciseness (a direction of precization) or greater specification. A resultant fairly precise and specific “version” of the theory is tested in various ways, including observation, but only as a stage in a larger movement. Whatever the success of a particular version, the scientist returns to the vague initial formulation (“the T_0 -formulation”), develops new hunches, and proceeds along a new direction of increased preciseness or of greater specification. If T_{11} and T_{12} are formulations at the systematic second step of “making more precise,” they are (by definition) heteronomous, clearly separated in cognitive content (see p. 129). The conjunction of two sentences that are more precise than a given one, say T_{11} and T_{12} in relation to T_0 , may or may not be logically inconsistent with each other, whereas conjunctions of competing versions of a theory will normally be mutually inconsistent.

If, over the course of time, various precise formulations have been accepted and then later rejected, and a new theory begins to gain a foothold, there is sometimes no energy left to consider another movement from the original idea. This situation is well expressed by saying that “the theory is dead.” But unlike humans, theories do not decompose after death; revival is easier for them than for us. After having been dead for a very long time (in scientific communities), Goethe’s theory of color has experienced a strange revival, but (of course) not as a theory competing with that of Newton (Holtsmark 1969). Cognitive competition requires cognitive comparability.

Possibilism and Permissiveness: Crazy Ideas and Connectability

In a notorious article in *Nature*, it was “shown” that the time of gestation of animals as different as cows and rabbits is a multiple of the number π . “Scientists have rightly refused to pay any attention to this evidence,” says Polanyi (Crombie 1963: 376), and he adds, *inter alia*, that “if scientists did not suppress the offerings of cranks, science would be swamped by trash.” I would rather say: if scientists and philosophers did not brush aside manuscripts that on the basis of very superficial reading seem cranky, their time would be totally consumed reading such papers.

Does the possibilistic slogan applied to theoretical impossibilities tend to encourage excessive tolerance in dealing with implausible, crazy, or irreparably vague conjectures? I do not think so.⁷

Let us consider one of the many factors determining which manuscript (among the formidable cascades of paper) to read carefully. Suppose I am asked to read a manuscript and start reading sentence p on page 20. It seems utterly crazy to me, but why? Because I think that p implies q , and q is obviously false. On page 21, I see that the author offers a very good reason for the view that, strictly speaking, p does not imply q but, rather, r . This interesting little triumph of the author makes me willing to examine reasons he may have for accepting r , a rather unlikely proposition in my opinion. If the author in a precise and convincing way supports r , the initial craziness of p has now abated a little. It may, however, require hundreds of additional tests to prevent me from concluding that among the innumerable seemingly crazy papers, this manuscript does not deserve the very high priority it needs to warrant close inspection. In this connection I would recall the notion of “connectability,” profitably used by R. von Mises and others, which is essential to most forms of conventionalism and to coherence theories of truth. If we connect pairs, triples, and greater classes of intuitively unlikely propositions, we shall rarely attribute higher degrees of likeliness to the classes of conjunctions. If confronted with a proposition that seems crazy, but is possibly true in the wide sense of “possible,” we normally require knowing how it connects with a large number of other propositions. In some cases, the connectability with a large class of propositions is such that the class “retroactively” strengthens the likeliness of the “crazy idea.” The idea “coheres” within a larger, consistent whole. This, for instance, is the case with certain ideas in Velikovsky’s *Worlds in Collision* and his published defense of them. But some people nevertheless ask for larger areas of connectability in order to change their verdict of “crazy!” Ultimately, the tribunal is that of philosophical systems giving definite meanings to propositions in “scientific” encyclopedias. The ideas of *Worlds in Collision* are such that, even if they are coherent with the vast body of historical sources appealed to (among others, the Bible), they still have to be confronted with modern astronomy and with general methodology and epistemology, the latter because of the author’s (perhaps) greater reliance on historical sources than on those of natural science.

Suppose researchers *P* and *Q* agree that *if* set *A* of rank dimensions is adopted, then theory *T* is superior to theory *U*; and *if* set *B*, then *U* is superior to *T*. We shall say they agree that the sets of propositions *A* & *T* and *B* & *U* connect, whereas *B* & *T* and *A* & *U* do not. But as metaresearchers we may ask: Are *P* and *Q* *factually* right? Is it the case, is it true, is it really so that *A* & *T* connects? The direct answer is not an answer that *A* & *T* connects (or does not connect). We shall assess the nature of the theorem “*A* & *T* connects” and, if things are complicated, the kind of research that is relevant in order to find the truth. On the basis of this investigation we shall adopt criteria of verification and falsification of the theorem. If metaresearchers *C* and *D* arrive at different sets of criteria—for example, after a rational discussion of epistemological issues—they might agree on the conclusion that if set *C* of criteria is adopted, “*A* & *T* connects & *C*’ connects” is true, whereas if criteria *O* are accepted, “*A* & *T* connects & *D*’ does not connect” is true. The conclusion is in terms of connectability.

But *C* and *D* may, of course, start a factual discussion about whether their conclusion is correct: do the connectabilities in fact hold? Thus at no level are there *only* questions of connectability. Questions of facts, of “agreement with how it really is” can be or must be posed at all metalevels. This argument is valid not only for the concept of connectability, but for that of coherence as well.

If a definition of truth in terms of agreement with fact is compared with a definition of truth in terms of coherence, there are strong reasons for rejecting the latter rather than the former. But if a criterion in terms of agreement with fact is compared with a coherence criterion, no definite conclusion is warranted before one knows approximately how tests of agreement with facts (a-tests) are compared with tests of coherence (c-tests).

Popper’s argument in rejection of coherence (Popper 1963: 226) is weak because he does not seem to distinguish definition from criterion and coherence from logical consistency.

The important question is not whether something is possible, but whether it is worth studying and working with. Research programs are not, and should not be, easily changed. A simple declaration that something we firmly believe to be impossible may well turn out to be the case is still not a sufficient basis for committing ourselves to research that might furnish fresh evidence for or against.

Then there is the difference between “wild” *theories* and metaphysical utterances of the lowest level of (research) preciseness. By the latter I mean what Popper sometimes calls “metaphysical” theories (“The world is my idea” and “Perhaps all is a dream”). They are not covered by what I have said in the foregoing discussion of possibilities because they do not in any way satisfy the requirements of a theory set down in chapter 3, p. 52.

If a scientist invites us to *work* with an unestablished theory that explicitly assumes the possibility of something that, on the basis of a justly admired, well-established, “complete” theory, is “proved impossible,” this implies that the new theory has already been worked out in sufficient detail for it to come into clear conflict with other theories. What scientists are apt to call “the philosophies of the schools” have no chance at all of coming into conflict with a theory, either with the kinetic theory of gases or with any other theory with scientific pretensions. The very notion of working with a theoretical idea implies a movement toward preciseness and specification. The slogan “Anything is possible!” is introduced for and *intended to operate* in research situations, and nowhere else. It has a built-in reference to “work.”

Working with Many Theories, in Many Ways: Theory Proliferation and Diversity of Praxis

As regards implausibility or “craziness,” it should be noticed that the possibilistic slogan only points to or suggests possibilities. It is not an injunction to work with *any* conjecture whatsoever. In addition to a so-called proof of impossibility (based on a well-established theory or “law of nature”), there may be *decisive* arguments against working with a particular hypothesis. Normally there are innumerable possibilities in a problem situation and a decision to pick out one approach for detailed consideration presupposes (needless to say?) additional qualification. Possibility is not enough for action. A decisive argument against working with a hypothesis is rarely a decisive argument against the hypothesis considered as a proposition. Work has to do with here and now, with persons, priorities, propensities, and time schedules. Work requires *someone* to work, whereas no one is called on to do anything about an abstract—however emphatic—assessment of truth, probability, likelihood, or possibility.

Therefore a decisive argument for accepting or rejecting something as a working hypothesis must be distinguished from accepting or rejecting something in the abstract as probable or improbable, true or false, likely or unlikely.

The possibilistic slogan tends to counteract the prevailing tendency to view a decisive argument against the *adoption* of a theory at a definite moment by a definite group as a decisive argument against the theory itself. It does not tend to encourage the adoption of any definite theory. That forces a reduction in the free inspection of alternative theories. The possibilistic slogan encourages serious consideration of alternative theories in the atmosphere of pluralism. It encourages this in defiance of the many so-called impossibilities. These are perhaps no more than expressions of current dogmatism, thoughtlessness, and narrowness of perspective. "I believe that, in the pursuit of physical science, the imagination should be taught to present the subject investigated in all possible, and even in impossible views . . ." (Michael Faraday).⁸

In view of the very limited time and capacity of a definite individual or a definite team, the vigorous pluralist approach in science can only be realized in large communities of researchers.

The above does not imply any agnosticism or any "*ignorabimus*" in relation to reality. "Through science and philosophy we get to know reality." There is no good reason to reject that slogan. But we cannot seriously impose any definite structure on reality to the exclusion of others with *correspondingly* high coherence, or with an *incomparable* degree and area of coherence due to divergence of criteria of coherence and relevance. Rather than supporting agnostic attitudes, the possibilistic slogan supports the Copernican view of science, against the medieval or positivist, in the terminology of Polanyi.

About Copernicus, Polanyi says:

But he was irresistibly compelled by the appearance of his own system to claim that this particular feature of the celestial order, though derived essentially from experience, was true and real. Thus did he make for the first time the metaphysical claim that science can discover new knowledge about fundamental reality and thus did this claim eventually triumph in the Copernican revolution. Such is the claim of science to know reality, that positivism disowned in our time; and it is this same metaphysical claim, now widely discredited, that I want to re-establish today.⁹

THE UNIMPRESSIVENESS OF IMPOSSIBILITIES

The claim of Copernicus as revealed in his theories is that of showing how the solar system really is. But there is no claim of irrefutability, of impossibility of retraction, in his work. Individual scientists indulge in pleasant fantasies concerning the importance and permanence of their contributions. The phrase “thus it is, and not otherwise” does not in itself indicate any absolutism when confronted with the large perspectives of scientific development through the centuries. Copernicus rejected the notion that his theory was only a mathematical tool; he stressed its physical character, but this does not directly relate to the questions of pluralism and possibilism.

The new historiographical trend shows the importance of the theoretical *idea* rather than any definite *exposition* of a theory. There is, however, another feature of a theory that is stressed: the conception of the *function* (rather than propositional or cognitive content) of the theory and its methodology within the total structure of scientific *activity*. The revolution that began with Boyle concerned *how to do chemistry*; it was not limited to a search for tenable or, even more narrowly, “true” hypotheses and theories. It therefore also has to do with what to expect from a theory, the motives of theorizing. One phrase dominates most of the answers: the aim of a theory is *to explain*. But it seems that a fairly comprehensive description of scientific theorizing cannot be in terms of explanation—if we do not wish to take the term in an excessively wide meaning. A more suitable term, because it is more general, is *to cover* or *to account for*; a theory aims at covering, and, if successful, *does cover* certain classes of phenomena, facts, laws, other theories, and it *solves* certain problems. As soon as one asks “What does coverage imply, and what constitutes a solution?” one sees that very different answers have been given, some of them using *explain* as a key term, but others are in explicit opposition to this idea or family of ideas (cf. the ideals of description, not explanation, in Mach, Hertz, Poincaré).

If a description of scientific theorizing tries to do justice to very different ways of doing biology, chemistry, physics, and astronomy, then this must affect the very essence of how “scientific theorizing” is conceived in its complete generality. A very broad metatheoretical concept is needed to help frame and place the plurality of kinds of theories and their methodologies. A pluralist approach is needed, otherwise one particular way of doing things is explained as an unsuccessful attempt at doing it another way.

Pluralism of Methodologies: Incomparability

The great Indian mathematician Ramanujan exasperated some of his down-to-earth Western colleagues by refusing to concentrate on *exactly* how he arrived at his astonishing theorems. He tended to revert to his assurance that the goddess of Namakkal inspired him with formulae in his dreams. Even if this methodological perspective opened up by Ramanujan seems rather exotic, its importance is unquestionable: it reminds us of the nonclosed character of the search for methodologies. Anything can happen to any methodology, however well established. But a new methodology must somehow impart to the defenders of the old methodology the impression of both success and universalizability. Ramanujan was perhaps the favorite of the goddess of Namakkal; she might inspire Westerners with wrong formulae.

Insofar as ideas on the function and methodology (“how to proceed”) of a theory are “built in” and assumed valid when the theory is advocated and used, it is cognitively (or at least logically) incommensurable with competing theories of the same comprehensive sort: If you adopt methodology M_1 , theory T_1 is confirmed and T_2 disconfirmed; if you adopt M_2 , T_2 is confirmed and T_1 disconfirmed. Or T_2 appears untestable from the point of view of M_1 , and T_1 appears untestable if M_2 is adopted.

The choice of a methodology is a choice of a conception or idea made on a wider basis than knowledge of the field of phenomena covered by the competing theories. It is an intrusion from the outside.

We have already mentioned the frequency of incommensurabilities and the resulting conceptual incomparability relation between “old” and “new.” The *phenomena* or *facts* said to be covered by a theory, when defined implicitly by the theory and the associated practice of research, cannot be independent of the theory itself. A very different theory that in superficial parlance covers the same phenomena, *cannot* cover the same phenomena—there are no theory-independent phenomena to be covered. (If the total classes of phenomena of theories T_1 and T_2 are C_1 and C_2 , and C_1 is identical with C_2 , there must be a set of semantical rules such that the conceptual structure of T_1 can be defined by that of T_2 and vice versa. But semantical incomparability is one of the necessary conditions of a characterization of theories as “very different.” With semantical incomparability at the theoretical conceptual level, semantical comparability at the obser-

vational level [by means of more or less arbitrary *Zuordnungsdefinitionen*] can only be ad hoc and not important for the life and death of the theories T_1 and T_2 .) In such cases, the new theory cannot “take care of” the phenomena or facts covered successfully by the old one. They are not defined and identified in relation to the new theory. Some designations may, however, survive the transfer. For example, “acid” and “vitriol” survived several methodological revolutions in chemistry. But, we must emphasize that in our use of the term *designations* here we are not merely speaking about words.

If there is a kind of isomorphy between the kinds of phenomena in the new and the old, the adherents of the new theory must be able to answer the “Where do you talk about such and such phenomenon?”—questions of the adherents of the old—with “To the phenomenon P in the old theory corresponds phenomenon P^* in the new.” The new theory does not say that P does not exist, nor does the old explicitly exclude phenomenon P^* —how could it?—but there are conceptual differences. P cannot be “named” in the new, and P^* cannot be “named” in the old.

The progress of the new over the old may now (in part) be said to mean that there are isomorphic relations of a P^* to any P in the old, and in addition, the new theory accounts for some P^* for which there are no analogues in the old, and which the old *cannot* accommodate.¹⁰

This way of seeing things also counters the tendency to view confirmation or disconfirmation as being of decisive importance. The superior quality, the “goodness” of the new theory, cannot be expressed in terms of falsification of the old, and the phenomena P^* , which are completely beyond the old theory, could never have been envisaged by the adherents of the old. However eagerly the adherents of the old theory would have looked for refutations, they could not have found any relating to those phenomena.

But such a conclusion may not be the last; there is no reason for not modifying certain well-developed concepts of confirmation, taking account of the relation of isomorphy between old and new “phenomena.”

Feyerabend (1970b) seems to argue along similar lines. The usual way to compare two successive theories is by an examination of consequence classes (Feyerabend 1970b: 219–20). When a theory T is superseded by T' , the accepted scheme of this comparison explains why T fails where it does, why T has been at least partly successful, and where T' makes additional

predictions. In a case study (comparing the classical celestial mechanics [CM] and the special theory of relativity [SR]), Feyerabend shows that these theories are incomparable. Their common class of consequences is empty. He goes on:

Even the case $c \rightarrow \infty$ (or $v \rightarrow \infty$) which gives *strictly identical predictions* cannot be used as an argument for showing that the concepts must coincide at least in this case: different magnitudes based on different concepts may give identical values on their respective scales without ceasing to be different magnitudes.

His conclusion is, “A comparison of content and a judgment of verisimilitude cannot be made” (ibid., p. 222).

All these reasonings seem to be based on a concept of “comparability” applied to the consequence classes of the theories to be compared. The existence of a nonempty class of sentences that follow from both of the theories is required to make the accomplishment of the comparison possible. The aim of such a comparison seems to be to decide which one is the closer to the truth (ibid., p. 220). There are cases, like the actual CM-SR case, which do not fulfill these presuppositions. The conceptual diversities are too great. With this I agree, but I want to object to Feyerabend’s scheme of comparison. I do not accept that it cannot account for the *relation* that permits him to speak of “*strictly identical predictions*” (ibid., p. 221), even if no precise comparison of consequences is possible. He says:

Now extending the concepts of a new theory T to all its consequences[,] observational reports included, may change the interpretation of these consequences to such an extent that they disappear from the consequence classes of earlier theories.

This I accept, but does the new theory in Feyerabend’s case cover quite a new area? Is it not a theory that *competes* with the older? How is it that the new theory can be said to supersede the older one?

As long as predictions from CM and SR are formulated at a high level of preciseness, they are incomparable and therefore never “strictly the same.” But, descending the ladder of professional preciseness, we arrive at the level of everyday talk about velocities and lengths. At this level, where our sentences are intimately connected with a *praxis* that is loosely shared,

whether we work with CM or SR, the predictions *are* comparable. One may say that, robbed of their precise frame of conceptual reference, what we compare are not predictions unambiguously related to CM *or* SR; the necessary discriminations are lost. But the main point is to admit the indirect but inseparable connection between the precise formulations and the everyday level formulations (“the T_0 -level”). If we do that we can retain our view that CM and SR cover roughly the same area, that they compete and sometimes yield different, sometimes the same, predictions and that in a very important sense SR (and general relativity [GR]) have superseded CM. Classical mechanics and special relativity are comparable and commensurable, but not at the precise conceptual level.

The methodological anarchism or dadaism of Feyerabend (1970a: 17, 21, 104) is compatible with my pluralism, but there is a major difference of emphasis. For me, the notion of philosophical systems is central. I require a strong, “puritan” stress on internal consistency, or rather coherence, between a researcher’s and a community’s logic, methodology, epistemology, ontology, ethics, and politics. The hedonistic “Do as a researcher what you wish and have a pleasant time” is qualified by the addition “and, if a philosopher by inclination or necessity, be clear and coherent in developing your synthesis.” Because of requirements in other parts of the system, one’s methodology in scientific matters *may* have to be rather rigid. Anything will *not* go.

The Heuristic and Systematic Role of General Systems: Metaphysics, Maturity, and Stagnation

There is a growing acknowledgment of the *heuristic* role of ideas developed in the main philosophical systematizations since the time of the pre-Socratics. Referring to the participants in a recent research colloquium, Paul Weingartner is able to conclude as follows:

Die Teilnehmer stimmten darin überein, dass sich bei entsprechend gewissenhaftem Erforschen und Zurückverfolgen von Problemen der Einzelwissenschaften bis zu ihren Grundlagen die Notwendigkeit der Erörterung metaphysischer Themen und Theorien ergeben muss und dass die Metaphysik eine nicht zu unterschätzende Rolle bei der Entwicklung und Weiterentwicklung der Einzelwissenschaftlichen Theorien spielt.

(Weingartner 1967: foreword)

The reaction against metaphysical speculation has often had a positive effect on the willingness of scientists to work hard experimentally, and year in and year out to perform monotonous and repetitious acts (endless weighing and boiling in organic chemistry, inspection of thousands of photos of tracks of particles in atomic physics, etc.).

“It has, no doubt, been worth the metaphysical barbarism of a few centuries to possess modern science” (Burt 1924: 203). But mature scientists who enjoy and use speculation in their work are still afraid that young talents skip the pedestrian and sometimes onerous aspects of research. Bondi, the cosmologist, having lectured on some fascinating speculative matters, closed with this advice, “I am delighted if I have interested you in this, but do not do any work in such speculative fields until you have done some good pedestrian work so people know you are a real scientist, not just a crank” (Bondi in Yourgrau 1970).

The acknowledgment of the *systematic*—not only heuristic—role of metaphysics in its relation to science is less conspicuous, but also increasing. Among the many valuable contributions to a shift in attitude, I would like to mention the work of Joseph Agassi (1964).

Marx Wartofsky (1967: 155) defines classical metaphysics as follows: “a rational—that is a unified, coherent and critically appraisable—world-picture; in short, a model of reality.” It is clear that a metaphysics in this sense will function not only heuristically, but also as a doctrine that suggests the form of future theories. Thus, the above-mentioned theory of levels suggests hidden-variable theories of subquantum physics.

Any adequate perspective of scientific development that takes account of the interdependence of science and metaphysics rules out the cleavage between mature and immature science. So-called maturity is a sign of professional isolation and stagnation.

According to Jean-Pierre Vigier, one of the leading physicists who has opposed the Copenhagen interpretation of quantum mechanics, the history of life on earth develops in accordance with concepts such as dialectics, contradiction, and totality. From Cuvier to Darwin, science progressed from formal to dialectical logic. Vigier and others—he mentions de Broglie and Yukawa—accept a theory of levels (*stufentheorie*) that suggests that there are processes and elements below the size of elementary particles and that research will have to penetrate that level and find the laws operating there. According to this metaphysics, there are an infinite

number of levels, each with a complete and specific set of laws, which, in their entirety, constitute an independent whole or totality (Vigier 1965: 65–85).¹¹

When we go from level n , within the realm of 10^{-n} cm to level $2n$ and enter the world of processes of dimensions 10^{-2n} (or $10^{-(n+k)}$, $1 < k < n$), a new science of mechanics has to be developed in order to take account of the more complex properties of reality. As part of this metaphysics of levels there is an “optimist” epistemology from which it follows that there is no level that cannot be reached by human research.

Behind the optimist terminology there is, however, an acknowledgment of accuracy as a graded magnitude, knowledge as refutable (p being known [as true or probable] at time t_n , not p [as true or probable] at t_2 , and p again at t_3). And when judging assertions such as “science takes over the role of philosophy,” one must remember the Fichtean, Hegelian, and Marxist sources of terminology that make “science” (*wissenschaft*) into a broad term covering systematic, interpersonally and interculturally precise but “dialectically” conceived so-called knowledge. What I shall here call general systems might therefore be covered by this term “science.”

Our perspective is that of systematic, but unending, expansive research—the “spiraling” character of a research project if left to itself. Therefore, we cannot ignore research in the social sciences, psychology, history, and other fields that have as much to do with ourselves as beings capable of understanding and carrying out research as with the objects of our understanding—“the world.” This means that in talking about heuristics and systematics of metaphysics, we might as well talk about the (great) philosophical systems, or, better, “near-total systems.”

Until now, a near-total system has roughly included basic or regulative ideas in ontology, methodology, epistemology, formal logic, theory of language (including semantics), theory of value (including aesthetics), and ethics. As part of certain systems, there have been argumentations against the meaningfulness or independence of ontology, or formal logic or ethics, etc. I do not think that either these argumentations of old or recent antimetaphysics warrant any special consideration. As an antimetaphysician, antiphilosopher, or adherent of pure *praxis*, one is caught up in the game as soon as one tries to justify one’s position.

Professional philosophers in the West are now studying, with perhaps greater eagerness than ever before, the general systems of Aristotle,

Epicurus, Thomas Aquinas, Descartes, Spinoza, Hobbes, Leibniz, Kant, Hegel—and of many others whose thinking can be reconstructed in the shape of a general system. Insofar as the historical systems are inspired by strong “visions,” or general attitudes toward the world, ourselves, and everything else, they are indestructible. There are no ways of probing them from the outside.

Because of the great cultural and social distances between the systematizers themselves, and between them and our time, utilization of their works must more or less take the form of free reconstructions. As they are originally formulated, these systems use too many terms and concepts from which we are alienated today. Every way of exposition, arguing, and derivation must be reconsidered in order to get maximum contact with the manifold of present-day ways of talking and doing things.

As an example of a contemporary high-level “metaphysics,” Wartofsky mentions Whitehead, but of course there are others, although they are not so well known in scientific circles. We may refer to the general views of Cassirer, Jaspers, Meyerson, Heidegger, Sartre, Kotarbiński, and others. The system builders do not always have the kind of scientific career or background needed to appease the “tough-minded,” but there is no standing obligation to appease them.

There are a large number of different ways to conceptualize the relations between a “metaphysics”—that is, a near-total systematization—*a general system*, and systematizations of scientific “results.” I shall refer to some opinions relevant to this issue that appear at least *prima facie* to be conflicting. Carefully elaborated, they perhaps need not be so.

The following unpretentious list tries to build a bridge between those who think that selected, more or less unsystematic, metaphysical ideas have been, and perhaps are even today, a potent source of scientific ideas, and those, like the present author, who believe in a great future for general systems in which philosophical ideas, genuinely and to a large extent, furnish scientific propositions with more precise cognitive meaning than they do when left to themselves.

1. General systems help scientists to *understand* science. Without metaphysics, science degenerates to mere doing, performing operations. What is done can be understood in terms of a metaphysics.

THE UNIMPRESSIVENESS OF IMPOSSIBILITIES

2. A science differs from a rational, precisely formulated general system only in scope. A science treats a part or aspect of reality in special ways (methodological requirements).
3. Science gets its theoretical ideas, its leading, regulative ideas mainly from general systems. They are elaborated in the specifically scientific way.
4. The members of a group must have some central shared beliefs as part of their similar general system—this is a prerequisite for the development of a science.
5. Metaphysical parts of general systems provide the original, irreplaceable myths that may be developed so as to yield the testable components that comprise science.¹²
6. Metaphysical views offer different interpretations of facts; they function as regulative ideas. Scientific theories are special developments of these interpretations. When a theory is “refuted,” the metaphysical view itself is abandoned among active researchers. (Agassi 1964: 191 ff.).

In what follows I take *metaphysics* to be another designation for “(near) general or total philosophical view or system.” The term *near* is inserted to avoid, within the framework of this essay, those interesting but perplexing problems that confront us if we push far in the direction of the notion of an *absolutely* all-embracing view or system. Problems of self-reference are famous examples. A system is partial or fragmentary if, but not only if, it does not in principle cover all questions relevant to each proposition of the system. An anatomical description of the brain elicits questions that are deliberately and legitimately excluded from anatomy—for example, physiological problems. The physiological description or theory excludes the mind-body problem, or at least many aspects of it. Characteristic of the great general systems is the program of answering or at least formulating *all* main or essential problems in *whatever direction they lead*, but leaving out any topic that only calls for subordinate treatment. Philosophy of logic does not include technical logic; philosophy of mind does not cover theory of rote learning.

The main points in general systems may normally be roughly condensed into a small group of nontechnical utterances, each having a characteristic ambiguity and vagueness, but also a primordial suggestiveness.

An example:

1. Nothing comes of nothing.
2. What is, is corporeal.
3. Some bodies are made out of others, but some are not. The latter are what the rest are made of.
4. The bodies that are not made out of others have no properties except bulk, form, and weight.
5. The human soul is corporeal and evenly distributed throughout the human body.
6. The human body transports perceptions to its soul.
7. Sense experience is the basis of all kinds of knowledge.
8. What is sensed in sense experience is reliable and true of reality.
9. The direct objects of sense are sense images, not the things in themselves. The images are themselves corporeal.
10. Two utterances that contradict each other cannot both be true.
11. An utterance that claims to express knowledge is only meaningful when it is about something that can be experienced.
12. Every joy is a good, every pain an evil.
13. Wisdom teaches that enduring joy can only be reached through generosity, justice, friendship, and group loyalty.
14. The unwise seek power and are capable of political domination, but the wise know how to neutralize their influence on matters essential to human happiness.

This set of “point-of-departure” sentences contains some ontology, philosophical psychology, epistemology, logic, semantics, ethics, theory of value, and political philosophy. The first ten points can be roughly attributed to Epicurus as interpreted by one of his great admirers, the German philosopher Friedrich Albert Lange (1873: bk. 1, chap. 4).

Philosophical systems are elaborations, systematizations, and precisizations of basic views suggested by key sentences and terms of the kind exemplified. One of the regulative ideas common to these systems is that of coherence, the general absence of logical contradictions and inconsistencies. To test this, systems of logic and methodology are developed as part of the total view. These subsystems show great variation when made precise. Another regulative idea is that of agreement with (the one and

only) reality—tested in various ways relative to the system’s inherent epistemology and methodology. The two regulative ideas are themselves incapable of being made precise without loss of neutrality in relation to the total manifold of systems. (The idea of such a manifold is itself incapable of being made precise without loss of neutrality!)

Implicit in my conception of a philosophical system with interpreted science as a genuine part is the principle of two-way criticism: scientific propositions, observations, laws, or theories may contribute to the weakening of a philosophical proposition and vice versa.¹³ The position of Lakatos is relevant here:

[W]e do not eliminate a metaphysical theory—as Wisdom suggests—if it clashes with a well-corroborated scientific theory. This would be a generalization of naive falsificationism. We eliminate it if it produces a degenerating shift in the long run and there is a better, rival, metaphysics to replace it. The methodology of a research-program with a “metaphysical” core does not differ from the methodology of one with a “refutable” core except for the logical level of the inconsistencies which are the driving force of the program.

(Lakatos 1968a: 180)

The main point here is the existence of common methodological maxims that make a two-way criticism practicable.

What can the experimentalist learn as experimenter from philosophy? Perhaps not much. But retrospectively one may note how ignorance of philosophy has impeded experimental research or has resulted in much useless labor. To take an example: Robert Boyle wasted his time carrying out experiments with the aim of refuting the theories of substantial forms—theories that, first, had long ago been abandoned by philosophers of his age and, second, were too vague to be refuted. When Spinoza read Boyle’s *Certain Physiological Essays*, he thought Boyle’s experiments had a worthier aim, namely to support mechanistic theories in chemistry, and criticized them on that basis. When informed by Henry Oldenburg, secretary of the Royal Society, about the real aim, Spinoza could not resist making the remark that he had not been able to persuade himself “that the very learned Mr. Boyle had set before himself in his *Treatise on Nitre* no other end than merely to show that the puerile and trivial doctrine of Substantial Forms, Qualities, etc., rests on a weak foundation.”¹⁴

By “science” I roughly mean the kind of science developed since the time of Galileo, with modern theoretical physics as the most notable

example. For arguments that this is only *one* kind, see, for example, the comparison by a learned historian, Joseph Needham (1963: 117–53), of Chinese with Western science.

Very little can be said *in general* about the two phenomena, philosophical system and science, even if we deliberately narrow the use of the term *science*. It has been suggested that philosophical systems have a greater vagueness, lack of clarity, and lack of logic. But preciseness or exactness may be very pronounced in a philosophical system. Johann Friedrich Herbart's philosophical psychology, a genuine part of his general system, is a good example. Empirical testability may be secured through long chains of mathematical derivations (a weak point in Herbart's psychology). On the other hand, *intersubjectivity* and *intercultural agreement* have never been greater than in the case of "modern" science. It is tempting to add to its list of characteristics quantitative methods and experimentation. However, even crude Baconian science proceeds by experiments of some kind, whereas the "system" of Galileo's and Newton's laws of motion, sometimes taken to be experimentally confirmed by Newton and inspired by Galileo's (doubtful!) experiments, may well be derived from the metaphysically loaded, nonexperimental physics of Rene Descartes. Remarking on the possibility of Galileo's influence, Brian Ellis says:

[I]t is much more plausible to suppose that Newton's laws of motion were derived directly from Cartesian physics, and that the only experimental evidence that was in any way directly relevant to the truth of Newton's laws was the evidence upon which Descartes and Huyghens supported their law of conservation of momentum. (Ellis 1965: 30)

Philosophy and science are interlocked in such a way that they can only be separated by making a number of more or less arbitrary distinctions.

A radical pluralism of approaches within a research community presupposes an adherence to the "live and let live" maxim that today perhaps is rather rare. Paul Feyerabend (1970a: 107) quotes Robert Merton, who tells us that the "organization of science operates as a system of institutionalized vigilance . . ." and adds:

In a warlike community of this kind proliferation will certainly lead to tension and nastiness (and there exists a good deal of nastiness in science, as well as in other critically rationalistic enterprises) but there is no need to combine proliferation with a war of all against all. All that is needed is less moralism, *less seriousness*, less concern for the truth, a vastly deflated "professional conscience," a more playful attitude. . . .

We might add that the concern for truth is essential, but the belief that it can be tested easily, and that when faced with two different approaches one of them must be nearer to the truth, is pernicious.

The use of the notion of a near-total philosophical system tends toward conceptual disengagement in the wars between schools and approaches. One acknowledges that *if* the differences are as deep as one could wish, clear-cut disagreements, such as we have when discussing facts, are not obtainable. Let the radically different approach live!

As it is not our task here to discuss all aspects of the complicated relations between metaphysical philosophy and science, I shall simply conclude by maintaining (1) that a theoretical idea that is part of a definite scientific theory may also be an idea within a philosophy, (2) that such an idea may well be worked out and made more precise and specific in *both* a professional philosophical system *and* a particular science, but (3) that the guidelines for the scientific exploitation of the idea are marked by stress on intersubjective (cooperational rather than operational)¹⁵ preciseness and testability.

Intrinsic Value of Research and Science

In the philosophy of science of Popper, Lakatos (1970: 162), and others, the progress and growth rate of sophisticated theory-centered science are highly valued. Sometimes it seems that only the achievements of the giants (Galileo, Newton, Einstein . . .) really count.

In contrast to this I shall stress the intrinsic value of research in general—not only scientific theory construction—among a growing number of the population, both those who directly participate in the professional life and also amateurs. The majority of researchers, the not very brilliant nor outrageously narrow-minded, determine the rate of growth. But in spite of some waste on research projects that no one enjoys, the overall picture is one of the intense satisfaction of a deep human urge: that of understanding and of a many-sided expansion and deepening of understanding. The growth rate is of secondary importance, especially considering the anarchic condition of politics: many of the results are still misdirected or used without responsibility and awareness of consequences. There is also, in the societies that stress competitive technical achievements, an overestimation of mere cleverness, brilliance, and intellectual prominence. This

severely limits the value of scientific activity. Lakatos divides research programs into progressive and degenerating, but some of his progressive ones are degenerating in the sense of having other-directed, status-seeking participants or of having acquired the character of a mere game. The above remarks exemplify valuations that are part of a philosophical system in which science is subjected to systematic valuation. It is clear that research policy is ultimately dependent (in part) on the larger system, which enables all human activity and all kinds of reasoning to be compared by considering a range of values, intrinsic and extrinsic.

By a research program, I mean a plan of how to use one's time as a researcher in the near future or over a longer period of time. Paradigms of such programs may be obtained from memos outlining the decisions of a group of collaborating scientists. They mostly contain speculations about what will be found at various stages of the research process and about how to react if "nothing" is found before certain dates. They contain strategic and tactical paragraphs, advice, rules, hypotheses, and hypothetical imperatives.

In spite of some excellent features in Lakatos's notion (or notions) of a research program, I think it wise to adhere to the above, more pedestrian idea of a program.

V

The New Historiography Applied to Itself: General Possibilism

The Discontinuity of Traditions and the Resulting Nonaccumulative Character of Scientific Knowledge

In view of its exceptional suggestiveness, let us start with the work of T. S. Kuhn. Roughly speaking, Kuhn suggests that a mature science develops normally within a tradition through acceptance of a certain way of “doing science.” The activity is, only in part, characterized by acceptance of a definite set of explicit theories, assumptions, and postulates as true and correct. Implicitly held views, presuppositions (à la Collingwood) contribute essentially to the tradition. Only a revolution, incited by persistent anomalies, makes the scientific community relinquish its loyalty to its tradition and take up a new way of “doing science.”

The results of a tradition N tend to be described within the new tradition $N + 1$ as mistakes eventually eliminated, or as lower approximations to truths established within the new tradition. In reality, however, there is, according to Kuhn, discontinuity between the old and the new way of doing science, which makes it impossible to do justice to the old within the framework of the new. And without a definite conceptual and practical framework, no scientific formulations intended to express *results* can be adequately understood. (The latter is implicitly assumed by Kuhn, and I shall also accept it with certain reservations.)

When scientists work consistently *within* a tradition, none of their experiments, observations, discoveries, or inventions can overthrow the dominant theory because these are framed and expressed in terms of that theory and presuppose specific implicit assumptions and a nonverbalized practice. But when persistent anomalies occur, some gifted scientists may try out entirely new ways of looking at things, and if they are compelling and successful, a new tradition will be inaugurated.

Because of the theoretical and practical disconnectedness of the old and new, there is *no genuine accumulation* of knowledge through the revolutions. There are reinterpretations of the old, certainly, so that there is a development, a progress as in philosophy or in the arts, but no simple broadening and deepening of knowledge or increase in approximations to a supertraditional and transtraditional truth. There is therefore no science *sub specie aeternitatis*.

Now even if we accept this view of the traditions and its resultant nonaccumulation thesis as true, there is nevertheless something that ought to be added.

From the point of view of general historical research, there has been, in the last thousand years, one important kind of accumulation: that of available documents and artifacts, manuscripts (observational journals, descriptions of apparatus), prints, machinery, collections of pictures.... More and more artifacts demand explanation. There may also be an accumulation, at least a very prolonged acceptance, of certain kinds of formulae, such as $F = ma$ and $S = \frac{1}{2}gt^2$. A historian will stress those materials that are retained in spite of variation of use, function, or meaning. This "accumulation," however, is noncognitive. The interpretations, meanings, and functions are not stored. Accumulation in a cognitive sense presumes persistence of function or meaning, and not only of tokens, signs, and behavior fragments. It is *cognitive* accumulation that the history of science does *not* show, according to Kuhn.

Let us then ascend to a metalevel and ask whether there is discontinuity of traditions in the history of historiography.

The Idea of Nonaccumulative Historiography Applied to Itself

In the Middle Ages, history was pictured so as to fit into a synthesis of theological speculation about God's interaction with natural events, and its methods were based largely on the doctrine of revelation and special authority. With Descartes new trends developed that changed the conception of history: on the one hand, conceptions within the frame of total systems, such as that of Spinoza, and on the other, methodological and epistemological positions in fierce reaction to dominant theological postulates. Thus *historical scepticism* introduced arguments against the decid-

ability of *any* proposition about the past. The age of enlightenment introduced a light-hearted belief in “rationality,” and convictions of a one-dimensional progress, both of which highly influenced the history of science. The concept of superstition was used to combat any position in conflict with dominant theories and hypotheses. But then this image was rudely shaken when the romantic trend set up new value priorities, cultivating the not-yet-clear, the endlessness of the main human projects, the place of irrationality within the seemingly most rational undertaking. The organic view, so dominant in many environments, stressed the broad historical setting of any enterprise, including, therefore, the scientific, and thus undermining the idea of linear progress. Then came the rising storm against the excesses of romanticism—the new era of the fight against speculation, with the victory of vast pseudohistories like that of Auguste Comte, based on a model of progress borrowed from the age of enlightenment, the reinstatement of the priority of certainty and of finite projects, and the cult of scientific knowledge as certain, stable, and applicable to any field, including history.

As to the outlook for general studies of historiography—the “meta-science” of the writing of historical development—the richness of mutually incompatible historical accounts (or “theories” in a broad sense) of one and the same event, doctrine, or epoch is best seen from a study of particular cases. Examples include the well-known vagaries and fluctuations in conceptions of Platonism¹; the mutually incompatible conceptions of the historical Jesus (admirably outlined by Albert Schweitzer [1913]); and more pertinently, of course, the fluctuations in conceptions of Aristotle’s physics. A new trend, very different from that of the first half of this century is gaining ground.² It was just as poorly foreseen as major changes in the conception of chemical elements or their numbers. To the great diversity of purely descriptive accounts of the past, we must add the diversity of philosophies of history—the Marxist, idealist, Hegelian, etc., conceptions of what history “is all about.”³ Today philosophy of history includes the hotly controversial methodology and epistemology of history.

These remarks are meant only to furnish a reminder of the problematic character of “appeals to history” in debates that touch the metastudy of historiography. “The history of science shows that . . .,” might well be replaced by the expression “There is at least one coherent conception of history of science such that it shows that. . . .”

Before Ernst Mach's inspired accounts of mechanics and optics, historiography of science received little attention from those who knew scientific research from the inside. It is not too difficult, however, to extrapolate backwards and construct images of science that are in harmony with earlier general historiographical trends. This offers a much-needed perspective for assessing current trends. An uncritical reading of the new, contemporary historiographers' exposition and criticism of the old dominant trend gives one, more or less inevitably, the impression that the new trend is the more correct. But appreciation of this very inevitability should in turn activate a desire to examine critically the sources of persuasion. These are then found to rest, in part, in the assumptions of the new, not of the old trend. *The exposition and criticism of the old is an essential part of the new.* The critical evaluation is thus, to put the weakest construction on it, not something constructed altogether independently of the new image. Let us apply this to the pretensions of the *new* historiography of science.

It seems that one is asked to accept it as *the* correct or adequate image. In my own case, I shall say that I can and shall accept it as based on at least one set of tenable assumptions, hypotheses, and observations. I accept it as an "image" that fits well into an outlook on history in general, and which is particularly well suited to certain contemporary research interests. Significant contributions to our understanding of the dependence of methodological frameworks on (research) interests are contained in the work of Jürgen Habermas (1967, 1968abc). Applied to itself, Habermas's theory of dependence announces its own limitation, its own dependence. This fits our possibilistic outlook.

More specifically one may ask: What kind or kinds of correctness or validity does one have in mind when deciding that a new image of scientific development is more correct or valid than a prior one? Considering the very indirect and complicated way in which the image, when expressed as a series of propositions, connects us with observations and artifacts of history, I propose that the kinds of correctness will have much in common with correctness of hypothetico-deductive theories. That is, observational propositions are, at best, *implied* by the theoretical proposition, given a set of auxiliary assumptions and postulates. On the other hand, nothing comparable to implication holds the other way—from observation to theory. An important consequence of this view is the plu-

ralist conception of images: there will be, in principle, an indefinite number of equally good images that fit the observations. But this anticipates a theme to be taken up later.

In what follows I shall attempt to show how Kuhn's doctrine of traditions, paradigms, or fundamental theories—a justly admired contribution to the new historiography—contains a fair portion of potential self-destructiveness if it is conceived as a doctrine intended to cover traditions, paradigms, fundamental views, and ideas outside the fields of natural science—for example, historiography itself. It should be noted, however, that such a conception of Kuhn's contribution is not the only possible one. We may, for example, take his utterances to be an invitation to adopt a certain kind of research program in metastudies of science—a different kind, for example, from that of Popper. But one need not, in all contexts, interpret his sentences in the same way.

Kuhn himself does not express any doctrine covering all traditions. Any argument against generality, however, is likely to provide only a thin wall, which is easily shattered by the pressure of parallel questions concerning the development of social science and history. For the kind of evidence that speaks against the doctrine of linear accumulation in natural science abounds in the humanities; the main difference being that dominance of one view or approach in the latter is more often restricted to particular countries or seats of learning. But these geographical limitations are not, of course, the essential point, which has to do with the effects of the dominance revealed in the history of historiography. A partial generalization from natural science to natural *and* social science is made by R. W. Friedrichs (1970).

Let us inspect Kuhn's crucial opening passage:

History, if viewed as a repository for more than anecdote or chronology, could produce a decisive transformation in the image of science by which we are now possessed. That image has previously been drawn, even by scientists themselves, mainly from the study of finished scientific achievements as these are recorded in the classics and, more recently, in the textbooks from which each new scientific generation learns to practice its trade. Inevitably, however, the aim of such books is persuasive and pedagogic; a concept of science drawn from them is no more likely to fit the enterprise that produced them than an image of a national culture drawn from a tourist brochure or a language text. This essay attempts to show that we have been misled by them

THE NEW HISTORIOGRAPHY APPLIED TO ITSELF

in fundamental ways. Its aim is a sketch of the quite different concept of science that can emerge from the historical record of the research activity itself.
(Kuhn 1962: 2)

According to this, a certain image of science has been dominant in the recent past; we can refer to it as number N in the general chronology of images. In our day a quite different conception, one may perhaps even say a new *concept*, is being created, a new image of science and of its methodology, and not through a piecemeal evolutionary process, but by a revolution, the historiographical revolution. Image number $N + 1$ is now, or soon will be, the dominant one.

What is the cognitive status of these hypotheses?

The process referred to seems very similar to what Kuhn, later in his book, calls a transition from paradigm N to a succeeding paradigm, $N + 1$, by a scientific revolution; except that this time the revolution is not in natural science but in the humanities, the *Geisteswissenschaften*. Such a transition affects all aspects of scientific activity, according to Kuhn, and it seems, therefore, that *the transition to the new historiography affects all aspects of precisely this new historiography*: the choice or selection of sources (corresponding to choice and selection of favored observational and experimental fields in mature sciences); the interpretation and conceptualization of the historical data (sources, documents); the hypotheses and theories (for example, about function of theories, chronological determination of discoveries, puzzle-solving character of normal science, function of anomalies, etc.); and the methodology (use of general historical methodology, study of the scientific community, research on “the research activity itself” rather than on their achievements in the form of theories).

But the persistence in time of historiographic reform or revolution disqualifies the new doctrine as more than image $N + 1$, the “textbook history of science” being image N . This disqualification seems to follow from the very conception of the “new historiography,” the conception centering on concepts of pervasive research traditions and cognitive discontinuity.

In spite of the role of the new historiography as a new paradigm of historical and systematic research centering on science (“science of science”), it is not explicitly conceived as such by its representatives. Their own perspective, which stresses the broad historical relativity of the narrow absolutistic pronouncements of paradigm makers and their followers, is not

applied reflexively to the pronouncements of the representatives and advocates of the new historiography. But this *lack of self-reference* is just what the new historiography would say we should expect from those who share a paradigm. The historiographer cannot at the same time be both inside and outside.

Kuhn expresses the optimistic belief that the doctrines of the new historiography can “emerge from the historical record of the research activity itself.” But this formulation belongs to a kind that, elsewhere in his book, he takes to reveal the unhistorical character of the *old* image of science. Characteristic of the old way of talking was just this tendency to pretend that scientific theories somehow emerge from the facts, the observations, and “the artifacts and materials”—to use an expression employed in the humanities. The pretension conflicts with the Mach-Duhem-Poincaré theorem.

The sources of the history of science are now richer, but there were also excellent sources before our generation. It cannot be said, therefore, that we are the first to have sources to inspect and that previous generations could never have hoped to talk about what emerges from the historical record of the research activity *itself*.

Our conclusion, then, is that the way in which Kuhn assesses the old and the new historiography fits in well with the image he draws of how scientists in a new tradition assess the relation between the old tradition and their own. He is caught in his own relativism. So far as I can see, the new historiography cannot, on Kuhn’s premises, properly claim any special status in relation to other historiographies. Therefore the outsider—for example, the metahistorian—who is interested in *the history of conceptions of history* is justified on Kuhn’s premises in taking his picture as only one of the many that have been offered since Aristotle.

The doctrines of the new historiography as conceived by Kuhn are extremely general and pointed. Thus, normal science is “a strenuous and devoted attempt to force nature into the conceptual boxes supplied by professional education” (Kuhn 1962: 5). What interests the metahistoriographer in this context is the relation of such a doctrine to the view that the social sciences—presumably including sociology, methodology, and history of science—have not yet reached the stage of maturity at which scientific activity may exhibit dominating theories shared by the community of scientists. The description by the new historiographers of the old, however, presents the old in just this way: as a general way of doing

(history of) science, with dominating views common in the community. But even if this picture of the old historiography is not accepted, we may foresee that historiography, by becoming more mature, will eventually reach the required stage. Once "firm research consensus" has been reached, historiographers of science would, according to the Kuhnian conception, make a strenuous and devoted attempt to "force nature" (in this case, historical reality and the development of the sciences) into the conceptual boxes supplied by professional education.

It is not at all a question here of whether the new historiography constitutes progress of some sort or not (I feel sure that it does), but of whether it would not be wise for someone who is not himself a professional historian to expect *many* (an indefinite *Mannigfaltigkeit* of) equally persuasive historiographical movements, trends, theories, and methodologies, and to take each as essentially a hopeful project, a program for research and understanding. Working on such a program tends to elicit more or less definite images of the future. The expectations for the future development of theorizing, whether monistic or pluralistic, seem to follow the general regularities of images of the future. In the words of one of the pioneers in "futurology," Frederik Polak:

Man's conscious striving to foreknow the future plus his partly unconscious dreams, yearnings, urges, hopes and aspirations for that future, periodically and successively, are condensed, crystallized and clarified into different sets of more or less specific, outlined and projective expectations or ideational goals. Such a set, at its end-stage of collective and positive, prospective and constructive development, may be called—introducing a new category of thought for social science—an *image of the future*. (Polak 1961: 16)

The striving of scientists, including historiographers, belongs to the most intense and well articulated; their image of the future plays a conspicuous role within their total view. Perhaps the image of theories merging into supertheories and of the succession of theories as a series of ever-closer approximations to one single theory, is expressive more of yearnings, urges, and hopes than of any realistic string of reasoning. An opposite image, however, might perhaps just as well be taken as an expression of the yearnings, urges, and hopes of sociologists of knowledge and historians who stress the irrational or discontinuous aspects of scientific

development. As far as I can judge, present methodological trends do not reject the possibility of working with hypotheses drawn from incompatible images of the future.

The new historiography of science has this profound character in common with Hegelianism, it surveys global epochs in which the actors, to some extent, must act like marionettes, not knowing their real historical function.⁴ Each epoch creates its own conception (image) of human history and interprets science within it.

By this view, however, actors from a given epoch cannot imagine that there have been, and will be in the future, other epochs of similar global character. This insight is hidden because of the discontinuous nature of the development of the human cultural enterprise (the variation of spirit), or *Zeitgeist*, from one epoch to the next.

Only the new historiographers of science can see through the epochs and tell us about their global character and the real function of certain kinds of activities—for example, “puzzle solving” (Kuhn), the character of which scientists themselves do not see through. They transcend their own historical situation, revealing what is hidden to others.

Those who, like myself, are not caught up in the act, but are simple, modest bystanders, may perhaps appreciate some of the accomplishments of the newest philosophy of scientific history, and at the same time vaguely conceive its nonglobal character, just as we are able to in the case of contemporary “mature” scientific theories. The bystander who has chanced to read drastically different general historiographical doctrines would seem well able to conceive the “unhistorical” character (in Hegel’s sense?) of the new historiography of science. But if the capacity to look at a string of historiographies from the outside should seem beyond him, who is left capable of discussing the issue at all?

In short, the application of the new historiography, to itself *hebt sie auf*, (with its stress on tradition and nonaccumulation), suspends it. But suspension (*aufhebung*) is not identical with refutation, and it is not necessarily an argument for abandoning a research program.

There is, incidentally, a touch of the Wittgensteinian approach in the work of Kuhn, and the arguments formulated by Gellner (1968: 377 ff.) in his rejection of the Wittgensteinian social science envisaged by Peter Winch also seem relevant to Kuhn’s position.

Winch acknowledges scientific activity to be a social activity. Concepts like “theory,” “refutation,” and “proof” have all developed in a social context; *therefore*, concepts used in that activity are social concepts. Let us inspect Gellner’s critical review of the consequences Winch draws. For our own purposes, substituting “refuted” and “refutation” for “married” and “marriage,” and “verbalizations in his scientific community” for “movements in church or registry office”:

[A]n event acquires meaning through the fact that it is conceptualized by the agent with the help of shared concepts—and for Winch all concepts are necessarily shared—and that the conceptualization is essential to the very recognition of the event. Example: a man “gets married” not merely by going through certain motions in church or registry office, but by possessing the concept of what it is to be married. If the concept were lacking, the same physical movements, in the same places, simply could not be classified as “marriage.” (1968: 384)

After substitutions and some other pertinent changes are made, we get:

Example: a man “gets refuted” not merely by motions of the hands and mouths of critics, but by possessing the concept of what it is to get refuted. If the concept of refutation were lacking, the same physical movements, in the same places, simply could not be classified as “refutation.”

From the point of view of Winch, then, to say today that Priestley was not really refuted by Lavoisier, in spite of his having been said to be refuted at his time, is nonsensical; within his scientific community, within the tradition, he *was* refuted. The meaning of “refuted” is to be found exclusively in the social relations between the users of the word. There is no external viewpoint, no independent standard. “What has to be accepted, the given, is—as one could say—forms of life” (Wittgenstein). Within the form of life of the scientific community of the time of Priestley and Lavoisier, Priestley *was* refuted. Getting married and getting refuted are only possible when we have the concepts, and the concepts form part of a definite form of (social) life. If and only if we take part in that social life do the concepts become meaningful, namely as vehicles in our specific social interactions. Therefore, in a different community, with different customs and practices, the concepts cannot be the same, and so incomparability and untranslatability result. No criticism is possible that transcends ways of community life.

What we say today using *our* concepts of refutation is utterly irrelevant when trying to *understand* what happened between Priestley and Lavoisier.

In the same vein Winch maintains that if a formulation does not express a hypothesis, but rather a true revelation within a community, it can never come to be anything else than a true revelation. “Oracular revelations (among the Azande) are not treated as hypotheses and, since their sense derives from the way they are treated in their context, they therefore *are not* hypotheses” (Winch 1964). Oracular revelations *are* oracular revelations. In a scientific community people do not take them seriously because it is a different kind of *community*, not because people see things more realistically in an absolute sense.

According to this social context- or tradition-absolutism, the methodological system of a community cannot meaningfully be criticized from outside. It can develop from within, but the frame is fixed.

Historiological Pluralism

The consequence of this Wittgenstein-inspired view is that insofar as there are historiographies, they are, as social interactions, part of a social system, a form of life, and are *specific* to this form of life. A historiographer may register the historical development of scientific activity (as understood within the system), but only within the boundaries of his system—that is, within a conceptual framework to which he and his results are bound.

This way of thinking leads to a *historiological pluralism*: There are as many historiologies as there are specific communities. And insofar as there is scientific activity, there are historiographies of science. As there are no external, no transsocietal standards of truth or correctness, all historiographies are equally valid. Criticism can only be immanent, not transcendental. Considering the absence of any meaningful comparison according to truth, correctness, plausibility or likelihood, confirmation, or any other graded predicate of cognitive import, they may be considered equally *possible*, using the term as in the Aristotelian tradition of *dynamis* and *potentia*. How many will ever be realized within finite time depends on the development and interdependence of societies on this and other planets. On our planet a definite kind, or family of kinds, is rapidly spreading over “the

industrial-technological-urban society." We may therefore expect a gradual narrowing down to one single unified historiography of science. But is this way of thinking clear, and is it consistent?

Such a philosophy inspired by the "form of life" holism *and* pluralism of Wittgenstein is only convincing as long as one does not admit that extremely different forms of life are already being compared by cultural anthropology and other social sciences, *and* that these studies at the same time are part of a Western kind or kinds of way of life. Historiography is part of a culture, and comparison of historiographies is part of cultural anthropology. Therefore, if we admit the existence of comparability in that general field, we should admit it in historiography of science. And if comparability in general is possible, why not comparability in terms of truth?

There are, however, other reasons for expecting and welcoming pluralism, and perhaps also possibilism. Let us consider some problems of observation.

The last hundred years have witnessed an increased flow of experimental results suggesting inescapable fluctuations in even the most elementary kinds of observation. Some are fairly constant, defining a "personal equation"; others are erratic and difficult to trace. Therefore not even on the most elementary level is there any basis for such utterances as "I saw what really happened," except as part of the language games of everyday life—that is, where the expression can be used irresponsibly enough for it not to seem very odd that one admits the next day that one was wrong.

In chapter 2 (page 23), we stressed that what is identified as the phenomenon observed depends on our metatheory of the process of observation. In the field of historiography, the problem of identifying the phenomena observed is still more conspicuous than in the natural sciences. If several different metaobservational theories are applied in historiography, a still greater diversity of images is expected to emerge.

The statements overriding my observation-statement may be of any kind. There is no commonsense empiricism such that observations are taken as a fundamental source of insight or truth. (Some experiments on nonphilosophers' empiricism are reported in Naess 1937–38a: 382 ff.). Any "empiricism" worth working with today takes broad experience, not narrow observation, as its key term.

It is an old maxim in the methodology of history that if there is only one eyewitness to an event, one may expect historical accounts to be categorical, whereas if there have been two or more, all documented, there will be an admission of uncertainty as to what really happened. The reason, of course, is simply that the records of two eyewitnesses tend to differ to an astonishing degree, whereas, that of one cannot. As everyone knows, the experimental psychology of witnessing has shown the vast degree to which a conception of what happens is determined by the expectations, orientations, dispositions, and emotional states of the observer.

It has also long been clear that in experimenting with higher organisms, the experimenter influences the behavior of the subjects—for example, by making them “verify” his prejudices.⁵ Ivan Pavlov explained in 1929 that on checking certain “experiments it was found that the apparent improvement in the ability to learn, on the part of successive generations of mice, was really due to an improvement in the ability to teach, on the part of the experimenter” (Gruenberg 1929: 327).

And experimental group psychology has shown how group membership and relations of authority, dependence, and so forth, introduce astonishing conformity into observations. Even the mere fact that there is a majority reporting something can have a profound influence on how things are perceived and conceived (cf. Asch 1965).

Therefore, among researchers alert to these findings, a narrator who solemnly appeals to an event “itself,” or to what “really” happened, is looked on with suspicion. A historian’s claim to be telling us what *really* happened in the French Revolution or what Hitler *really* did, will probably be interpreted by his colleagues as an effort at crude persuasion, or as irony. The more or less *irreducible multiplicity of versions* and their finite lifetime are taken for granted by historians.

But just as in persuasive political historical accounts, we find in texts in philosophy of science expressions intended to make us believe both that a definite version of what happens in a laboratory is the only correct one, and that the narrator has seen all that is worth seeing.

Claims about what “*really* happens” in a laboratory or what scientists “*really* do,” however, are made by narrators who feel the need for an undisputable observational basis for methodological doctrine and any other doctrine that is relevant to the philosophy of science.

"Let us inspect what the scientist *actually does*," "let us inspect *actual scientific practice*," how measurement "*has actually functioned*," "let us ignore what he *says* and *see what he does*"—such phrases are very common, not only in texts by P. W. Bridgman, but even in the writings of some of the new historiographers. I take it as an indication that they engage in rhetoric or have not applied their own basic views about scientific development to their own historiography.⁶

But if reporting on a *praxis* is reporting on *actions*, and not only on fragments of behavior, and group adherence is also involved, only a very simple faith can make one try to reduce the number of versions to one.⁷

The Mach-Duhem-Poincaré principle, if applied to reports of actions, leads to a doctrine of indefinite multiplicity of theories, all of which are equally well suited to cover the reports. That is, there is no inductive method that would make theories and hypotheses about scientific activity, viewed as sets of actions, into valid inductive inferences from eyewitness reports of behavior. There is no logical compulsion; as in physics, implications go *from* theories, hypotheses, auxiliary postulates, assumptions, sciences, and initial conditions *toward* observational reports—not the other way. In this realm of action, too, by implication, we may say with Lakatos: "Truth does not flow upwards."

Or is all this wrong? Is there, after all, a basic difference between the natural and the social sciences, the latter being subjected to the methodology of hermeneutics, philosophical anthropology, *Geisteswissenschaft*?

The Mach-Duhem-Poincaré thesis holds for the relation between, on the one hand, observation of actions (doings, not mere behavior-fragments) and, on the other, theories covering the actions—except that there are special methodological rules, corresponding to different doctrines of action, to be obeyed in such observation. We cannot directly "see" what another person does, even if this seems fairly obvious among good friends in favorable circumstances. A change in circumstances (due to war, business, divorce, illness . . .) can make behavior ambiguous and lead to a reevaluation of past behavior. And that involves reclassification ("I always thought he was doing such and such, but he wasn't").

Then again, several "doings" may be related in such a way that one is part of the other—we (1) buy a newspaper and (2) look for the arrival of a violinist as part of (3) the entertainment of a guest. If the doings are complicated, as they are in the case of scientists in laboratories, one cannot

trust the actor to give an adequate account—if he thinks you wish to help, he says one thing; if he thinks you are a nuisance, another; and if both, a third. And his account will, in any case, reflect his special intentions at the moment more than his basic conceptual frameworks. So unless you share them, you have to be careful; the two of you see quite different things. The plurality of conceptions, even among presumably equally competent scientists, is quite astonishing.

Accordingly, there is no basis at all for the assumption that we can single out one unique description of use as the correct one. One may wholeheartedly accept that reality is one without accepting that there is only one correct description of it. “Do not listen to what they say; see what they do!” is sheer infantilism if interpreted as a proposed guarantee of access to some *definite* way in which terms and sentences are “actually” used. Of course, fragments of verbal as well as nonverbal behavior are relevant, and what a scientist “does” includes his utterances. But a person who is observing the scientist’s actions is not in a better position to describe those actions than is the scientist himself. And there is certainly not just one description that he can give. There is no end to the different characterizations, some mutually consistent, others inconsistent, that a researcher on doings can offer in responsible social research.

If two witnesses of what is done in a definite laboratory on a definite day differ widely in their descriptions, we may analyze the differences and find them to depend, at least in part, on complicated sets of expectations, evaluations, and assumptions about the wider goals and aims of the activity on that particular day in that particular laboratory, but also on what is here called their metaobservational theory—be it conscious or not. Articulated in the form of assumptions, propositions, and (postulated) rules, the background of the two descriptions might be formed as two systems. Taking “if p , not r , is assumed or postulated, then q ” as consistent with “if r , not p , is assumed or postulated, then non- q ,” the two descriptions $[(p \ \& \ \bar{r}) \supset q \text{ and } (r \ \& \ \bar{p}) \supset \bar{q}]$ may be consistent even if their propositions (q and \bar{q}) are mutually inconsistent. And they would *both* add to our information about what was done in that laboratory on that day. Thus, the pluralist view is, heuristically, a relationalism, not a relativism; that is, each description is conceived in its relation to a system and is assessed immanently in *that* relation. The following are some conclusions:

1. Arguments today *against* the applicability of the new historiography theses (based on discontinuous, all-embracing traditions, and nonaccumulation of scientific knowledge) to the new historiography itself do not decisively outweigh the arguments *for*.
2. Applied to itself, the new historiography is just *one* way of doing history, a tradition No. $N+1$, and when articulated and made scientific, or pseudo-scientific, expresses *one set* (or one class of sets) of fundamental postulates, assumptions, definitions, and rules (recommendations, prohibitions, etc.). As in the case of physical theorizing, rules, conventions, and empirical elements are intimately interwoven, supporting neither extreme conventionalism nor naive empiricism.
3. To the outsider tentatively working out other sets, just for the sake of a survey of coherent structures, the new historiography appears as a "systematizable" possibility—a structure that is neither probable nor improbable, neither correct nor incorrect, but nevertheless *tenable, workable, and valid*—that is, valid as a fundamental systematizable possibility as part of a philosophical system.
4. Without himself in any way renouncing research, at least in the form of explicating possibilities of the most comprehensive kind, the interested outsider is grateful to those who work out a new way of doing history of science, and grateful for both the large visions and minute details offered by the participants.
5. The sets of fundamental postulates and assumptions implicitly adopted by historians of science working within a tradition are not specific to their discipline, but part of more general ways of doing research and asking questions. They may be conceived as expressive of general views, "metaphysics," or philosophical systems.
6. If one (with Kuhn) accepts, as part of one systematizable possibility, the thesis that research within a tradition only "gets going" when a community of scientists who share fundamental assumptions is formed, and also accepts the validity of all fundamental sets, then scientific results and achievements, as *understood* results and achievements (and not only as filed printed matter, tapes, and photos), must be accorded a multiplicity of interpretations of the second-order variety. The first-order variety stems from the one-many relation between observation and theory, the second-order

from the one-many relation between observation of scientific activity and historiographical metatheory.

But this leads to a final topic.

General Possibilism

A superhuman scholar, able to interrelate all dominant scientific theories at a given time, might be said to obtain a “scientific worldview.” Such an expression, however, is misleading in at least two ways.

First, by “scientific” we could refer only to what scientists, without opposition from colleagues, happen to assert and publish at a given moment. But then “scientific” would be taken largely as a sociological, not an epistemological or a methodological, concept. Dominance to the point of lack of opposition is seldom acquired, and, if acquired, it tends not to last long. Any synthesis would therefore be largely arbitrary from an epistemological point of view, and its formulation would tend to be out of date before its date of publication.

Second, an integration of the professional texts is dependent on ontologies that are not results of research but derived from everyday life or philosophy. The expectation of a definite scientific worldview (*wissenschaftliche Weltanschauung*), or successive approximation to such, is based on crude misconceptions of the scientific enterprise.⁸ Science has no autonomy in relation either to philosophy or to conceptions of everyday life.

What surveyors of research can offer as a partial substitute for comprehensive worldviews is, rather, a kind of catalogue of skeleton encyclopedias.⁹ Each might cover the whole world or “all there is,” and each may be internally consistent, but they would nevertheless be mutually inconsistent, or strictly speaking (see p. 130) incomparable because of mutual untranslatability. This possibility is the offering of carefully articulated individual *systems*.

A researcher eager to contribute to a department of science may not need such a picture in his research. He may be interested only in a tiny part of one of the pictures, or he may even find it heuristically necessary to work with an inconsistent combination of two. Or he may even neglect the philosophical distinctions required to arrive at a definite picture. The definiteness of his intentions may remain subphilosophical.

Few quantum physicists offer the philosophical public a fair chance to make a choice of how to integrate physics in their philosophy. One of the few is Bernard d'Espagnat (1965), who offers three philosophical interpretations: "... at the moment there is a true freedom as to choice face to face with fundamental problems."

Proliferation and pluralism of theoretical ideas and programs are now positively valued by Popper, Lakatos, and Feyerabend for methodological reasons, but only in physics and adjacent fields. When it comes to philosophy—I think now of attempts by great systematizers like Aristotle, Thomas, Descartes, Spinoza, Kant, Hegel, Marx, and Whitehead—it seems that a corresponding proliferation and pluralism are negatively valued. But on what grounds does one envisage growth through nonconformism in physics, but not in philosophy?

Creative physicists are adopting, and presumably will continue to adopt, mutually inconsistent views, all of which are sources of inspiration to researchers whose fields are broader, covering the relations of physics to society or to wide areas of scientific and philosophical systemization. To try to shut off the pluralist sources of inspiration is not only a methodological but a general cultural evil.

To take an example: The fight between proponents of conceptions labeled "idealist," "instrumentalist," or "realist" is largely barren unless the explicitness, comprehensiveness, and consistency of each *kind* of (allegedly) incompatible conception are worked out with the utmost care. Research promoting this sort of analysis, should, at the moment, be higher priority than attempts to show that only one of the vaguely outlined conceptions is correct.

What holds for physics holds for all other sciences today. Fundamental questions are given more or less vague and ambiguous answers. These questions provide centers of confused, partisan debate that have the primary aim of showing that one particular view is the right one. The more precisely and the more comprehensively the views are elaborated, the less chance there is of monism; a plurality of systems are created that stand out as important, workable *possibilities*. Increases in preciseness and explicitness inevitably involve thinking along the lines of a total philosophical system.

The dissimilarity of methods, pretensions, focus of interest, logical instruments, and other features closes, at least temporarily, the road back to sloppy monism.

Whatever the value, or lack of value, of a variety of scientific world pictures for the researcher in his daily work, there can be no question, to my mind, of the cultural value of such systematizations. The history of philosophy teaches us about the gigantic general systems created by outstanding personalities, each supported and elaborated in relation to a tradition or set of traditions (in the case of Spinoza, for example, medieval Jewish, Renaissance Italian, and rationalistic French traditions). No one can tell to what extent there will be original creations of this kind in the future. But with the pervasive role of scientific research in the years to come, there will at least be the more modest task of worldview typologists and systematizers—coordination and mutual elucidation of the materials derived from science and philosophy.

The relief from pressure toward conformity seems to me to offer great political advantages. Possibilism tends to diminish the conforming effect of science on society and on the individual. It increases the personal freedom in choice of philosophical principles by furnishing precise and elaborate alternatives.

When science was still frowned upon by political rulers, it was important for the researcher to fight for his position and even for his life, but now things have changed: rulers largely depend on scientists and must keep in favor with them. “Scientific” is a label that carries immense prestige in Western as well as some Eastern countries. The prestige is used by powerful “vested” interests to narrow the range of what are considered tenable views. This pressure is rarely counteracted by eminent scientists, who tend either to be retiring and uninfluential socially, or to be absorbed in particular approaches that make them unwitting supporters of crude dogmatism. Thus, today it is not by its own theoretical inclination, but through pressures on the scientific enterprise as a whole, that science is largely, but of course not consistently, moving in the direction of a *unity of outlook*, a “scientifically” sanctioned conformism.

The political consequences of such a “scientifically” sanctioned conformism have been a steadily recurring theme in the so-called Frankfurt School of sociology and philosophy, represented by authors such as Max Horkheimer, Theodor Adorno, Herbert Marcuse, and Jürgen Habermas. Compare the following from Horkheimer and Adorno’s *Dialektik der Aufklärung* (1969: 4):

THE NEW HISTORIOGRAPHY APPLIED TO ITSELF

Die Angst des rechten Sohns moderner Zivilization, von den Tatsachen abzugehen, die doch bei der Wahrnehmung schon durch die herrschenden Usancen in Wissenschaft, Geschäft und Politik klischemässig zugerichtet sind, ist unmittelbar dieselbe wie die Angst vor der gesellschaftlichen Abweichung.

In this situation it is imperative to stress the freedom of choice that remains despite the overwhelming mass of highly reliable detailed “knowledge” added every year through research and crudely communicated to the public as “authoritative.” But without a foundation in radical pluralism, any stress on choice tends to be insincere. Those who, for lack of philosophical education, see a lot of “hard facts” in textbooks, and mistake increase of area of agreement for increase in truth content, cannot honestly combat the ensuing conformism, any more than can the intensively, personally engaged researcher who is “in love” with a definite methodology or theory. Radical pluralism of research programs is a powerful liberating force.

People still consider a person’s general outlook, his view of life and the cosmos and world history, as part of his whole personality—or at least within many subcultures a tendency to pay lip service to such a conception of a person still persists. But popularized science, whose present tendency in the matter of worldviews is nearly always toward the authoritarian and monolithic, influences us in the direction of either abandoning all our efforts to retain a general outlook, or of forcing it into conformity with the dominant world picture.

A worldview typology that uses different scientific world pictures and different philosophical systematizations as its basis will show how freedom of choice increases as a view draws closer to the fundamentals—ontology, methodology, epistemology, philosophical logic, anthropology, and philosophy of history. In this way I see such a typology as a source of cultural diversity and personal integration. It would comprise a new trend of popularizing science, inviting the general public to study and enjoy diverse interpretations in their comprehensive settings.

In what way freedom of choice increases might be better explained by the concepts “definiteness of intention” and “preciseness,” which were introduced in my *Interpretation and Preciseness* (1953b [SWAN I]). The latter

can be sketched as follows: a sentence T_i is *more precise than* a sentence T_0 , if there is at least one interpretation that T_0 admits, but T_i does not, and if there is no interpretation admitted by T_i that is not also admitted by T_0 .

Preciseness thus defined is a transitive relation, and definiteness of intention can be measured with reference to chains of “precizations,” $T_0, T_1, T_{11}, T_{111}, \dots$, where T_{111} (and T_{112}, T_{113}, \dots) are more precise than T_{11} (and T_{12} and T_{13}) and T_{11} more precise than T_1 . If a person fails to discriminate at the level of T_{111} , but succeeds at the level of T_{11} , T_{111} is said to be a transintentional precization to his set of discriminations. All measurements are relative to discrimination grids that function as reference systems.

The following diagram illustrates the various concepts:

Figure 4. Illustration showing the levels of discrimination and preciseness. If an intended discrimination can be located at level 3, it is more definite—more precise—than a discrimination that can be located at level 2 but not at level 3.

Applying these concepts to the pluralist thesis, or view, I suggest that we present, for instance, the various expositions of physical theories at the T_0 level. It is a relatively neutral level only because of its low level of philosophical discrimination. The professional expositions have, of course, great preciseness and great definiteness of intention in professional, scientific directions. But what concern us here are the broad, nonscientific, untechnical interpretations of terms like *matter*, *particle*, *mass*, and *force*. These interpretations furnish our common ground in discussions. In this respect, the expositions are at the T_0 level. Any sufficiently vigorous effort to uncover and articulate the full cognitive meanings of such terms reveals

the philosophical idiosyncrasies of the author. Ultimately, the same philosophical system is presupposed. It is only within such a system that it is possible to offer precise reasons for the decision to continue working with one theory rather than any other. The requirements that a choice must be rational and the results coherent are, so to speak, formal requirements whose contents are determined by the value norms and postulates of the adopted system. Taken in isolation, they are not sufficient to advise the scientists.

From this it follows that it is problematic to compare scientific theories or images of the scientific enterprise that are made precise in different philosophical directions. Such comparison must presuppose a common standard or value system. But a standard can only be valid within a particular philosophical system. If the theories or images refer to philosophical systems that are sufficiently different, they are incomparable. Both are to be considered *valid*, but as this concept refers to a definite philosophical system or class of systems, one cannot say that the theories or images are *equally* valid. A further discussion on validity appears below.

I also want to point to another consequence of this view. It is what we may call the *indeterminacy relation* between preciseness and definiteness of intention on the one hand, and neutrality and comparability on the other hand. If one starts making an exposition of a theory more and more precise in a definite philosophical direction, what is gained in preciseness is lost in philosophical neutrality and comparability, and vice versa. This result can also be extended to expositions of images of scientific research.

A monolithic, soul-shrinking jargon still prevails in discussions on worldviews among creative scientists. It is as if the prestige of science as a truth-seeking project depended on the emergence of one definite world picture, *the* scientific world picture, as opposed to all the unscientific ones—the confused, vague, irresponsible metaphysical views, the grand illusions of the religious believer and of the cognitively irrelevant artist.¹⁰ A consequence of this is that increase of uniformity of opinion is cheered as if it were a reliable indicator of increase in truth content, neglecting the possibility that it is the urge to conform that prevails.

Now, I should have to admit that although the foregoing remarks may have a sufficiently clear sense as suggestions within general philosophy of culture and politics, they are highly resistant to precise formulation

in relation to philosophy of science. Tentatively, however, I propose the following formulations:

1. *All consistent, comprehensive points of view have a non-zero status of validity.* As to comprehensiveness, the points of view must explicitly include logic, methodology, semantics, and ontology—or a set of arguments to the effect that a body of rules and assertions of one or more of these kinds is unnecessary, nonsensical, or has some property justifying its absence from a maximal comprehensive view. Instead of *comprehensive*, we might use the terms *near-total* or *near-global*. Instead of *points of view*, we could substitute *view* or *system*, but not *doctrine*, since norms, postulates, and assumptions are usually thought to be absent from doctrines.

The term *validity* is used in such a sense that the first links in argument chains within a particular system are taken to be true or correct—until further notice. That is, it may turn out that acceptance of the first links (initial sentences) in an argument for a methodology M_1 entail acceptance of some observation sentences that contradict some other set of first links in the system. It has then to be decided whether to modify the methodology M_1 or dispense with the initial sentences affected by the observations. If this cannot be decided *within* the system, a modification is called for that, strictly speaking, means the abandonment of the system in favor of one resembling it.

The somewhat awkward quasi-scientific expression “non-zero status of validity” is preferred to “true,” “valid,” and “correct” for several reasons. Negativity (non-) is used to stress a minimum assertion. It is untenable to proclaim that validity is *absent*. A kind of validity is present. But what kind? “True” has too strong associations with “agreement with reality”; systems constitute conceptions of reality, rather than mirrors or isomorphical structures. “Correct” is too suggestive of measurement against an already established yardstick.

2. *Reality is one.* This short sentence functions as a pronouncement against those who think that the acceptance of the above thesis of equivalence of validity goes against ontological realism. There cannot be but one true system, it is said, because there is only one

world, or reality. If two systems are mutually inconsistent, they cannot both be true—that is, agree with reality. But the relation between system and reality is not one of mirroring or copying, not even one of structural isomorphism. Therefore:

3. *Two mutually inconsistent systems may both correspond to reality.* The view we have of the relation of systems to reality *need* not be of the special kind that makes it impossible for there to be many mutually inconsistent systems covering the same reality or part of reality. The rules of use for the term *reality* make it a kind of “regulative idea” in the sense of Kant. They do not make it represent a definite structure or substructure.
4. *A comprehensive and consistent point of view is not something a person (or community, or society, or epoch) can “have.”* This strange assertion is needed to counter those who equate the equivalidity thesis with what they call “voluntarism” and “subjectivism.” One can, as a person, without restrictions, *choose* one’s philosophy or metaphysics and adopt the kind of language one wishes to use. So, according to this perspective, the particular comprehensive view one adopts is purely a question of personal choice. But against this I hold that if an explicit choice is made, and based on a scale of priorities, one already *has* a very substantial part of such a comprehensive view. Any view that has the required degree of comprehensiveness is such that a whole person cannot stay outside and choose. If a person is, nevertheless, said to “have” such a view, it must be regarded as part of his personality. He cannot step out of his own skin. But he can change. And therefore “his” view may change.

Here I am only making use of the vague distinction stressed by Gabriel Marcel between being and having. A complex entity like a community, a society, or an epoch, can be said to “have” a comprehensive and consistent view only in a rather general, vague sense. There are trends, forces, and traditions that dominate the overall picture when seen from the outside (by the historian). But these trends, forces, and traditions are in part constitutive of the collectivities; we do not find the comprehensive views inside the community, society, or epoch. They are integrated in such a way that the community minus the tradition would not be that community.

And they are not to be identified with theories that the members of the community articulate and call “our view of life” and so forth.

5. *Points 1 through 4 are not capable of being made precise beyond certain (ill-defined, modest) limits of definiteness.* That is, any effort to construct a precise, professionally adequate theory (doctrine) of comprehensive points of view, including a “typology of possible worldviews,” is bound to be self-defeating because it requires an elaborate conceptual taxonomy or framework, and there are no such systems that are neutral in relation to the comprehensive points of view to be classified. They can each include a metasystemic doctrine, but the variation of systems cannot be maximal. The efforts of Georg Hegel, Wilhelm Dilthey, Karl Jaspers, and others to erect a general typology of *Weltanschauungen* show the dependence of their taxonomy on their particular comprehensive views. Hegel forces his framework on *his* classification; Dilthey imposes his historicism on all systems; and Jaspers lets them all float in a kind of Kierkegaardian pseudopsychiatric medium.

Series Editor's Introduction

Arne Naess — A Wandering Wonderer: Bringing the Search for Wisdom Back to Life

[The pre-Socratics'] attitude, in the main, was genuinely scientific whenever it did not merely embody the prejudices of their age. But it was not *only* scientific; it was imaginative and vigorous and filled with the delight of adventure. They were interested in everything—meteors and eclipses, fishes and whirlwinds, religion and morality; with a penetrating intellect they combined the zest of children.

From this point onwards, there are first certain seeds of decay, in spite of previously unmatched achievement, and then a gradual decadence. What is amiss, even in the best philosophy after Democritus, is an undue emphasis on man as compared with the universe.

Bertrand Russell, *History of Western Philosophy*

When the full scope of Arne Naess's philosophical contribution is examined carefully and placed in context, it will very likely be viewed as one of the twentieth century's most significant and enduring.¹ Naess has made bold and innovative contributions to conventional academic philosophy and social research, particularly in the areas of behaviorist epistemology, empirical semantics and communication theory, scepticism, scientific and cultural pluralism, Gandhi and Spinoza scholarship, normative systems theory (as a general approach for exploring premise-conclusion relations), and the very idea and relevance of total systems (total views in Naess's lingua). Perhaps even more significant—although one should not view it as distinct or decoupled—has been his commitment to reconnect philosophy to life experience. This effort is similar to Bertrand Russell's in that it has been particularly pronounced in later life. Naess, however, carries this com-

mitment to expand philosophy's sphere of concern to life in general and the Earth. Essential to this endeavor, is the mature Naess's radical initiative to reconceptualize reason expansively, to integrate reason with emotions and feelings *in practice*. In some cases this includes using mythopoetics to make a case or communicate a point.² What makes Naess so special is that even while paddling against the current, he exhibits tremendous optimism and openness, joy, and a disarming, infectious playfulness.

Naess strives to *live his philosophy*. For more than thirty years, he has sought to reshape the philosophical debate by drawing from and building on his previous work to outline a nondualistic, nonanthropocentric philosophy of life that affirms the ultimate unity and interdependence of all living beings, while maintaining their individuality. His philosophy celebrates the Earth's richness and diversity—both cultural and biological. That said, one of the main purposes of the *Selected Works of Arne Naess* (SWAN), however, is to provide you, the reader, with the resources to make your own informed judgment regarding the significance of Naess's philosophical legacy.

At age ninety-two, Arne Naess has lived a long life filled with wonder. In his words, he has “seen life”—traveling the world, spending significant periods of time on every continent. He has experienced the world somatically and intellectually in concert as one mind-body—as a being—and seen more than most of us can imagine.

When Naess was born, Archduke Francis Ferdinand was alive, automobiles were in their infancy, and most homes did not have running water. Home refrigerators had just begun to be produced. Television and computers were only imagined. Only a few years before, after being contemplated for millennia, the first controlled and sustained powered flight took place, ushering in a period of ever-accelerating transfer of materials and information, but not necessarily a commensurate increase in knowledge or wisdom.

Consider that Naess has lived through two world wars (and too many “limited” conflicts to count), the rise and fall of the Soviet Union and East Germany, the “liberation” of India and Pakistan, the onset of climate change, and the hastening of “global terrorism.” He has been the beneficiary of tremendous medical advances and unprecedented economic growth, and he has seen the ravages caused by escalating consumption, globalization, and disparities in both income distribution and access to resources. He is part and product of humanity's largest growth spurt. And he has witnessed the most significant loss of cultural diversity and the onset of

what may become the planet's greatest extinction crisis—but is surely the greatest extinction crisis ever caused by one of Earth's own species. Naess has also seen and, at times, participated in the many hopeful responses to these ills—the peace, social justice, and ecology movements; nonviolent actions to support antiglobalization efforts and protest dam building; voluntary simplicity; conservation biology; wildlands philanthropy; bio-regionalism; green business and architecture; ecological design, economics, engineering, and restoration; and sustainable agriculture, forestry, and fisheries management.

Everyone is influenced by the times and events of his or her day. The “prejudices of our age” filter into our lives and work more or less consciously and actively, but at a minimum they enter passively. What is the mature Naess's approach to philosophy, how is it a uniquely self-aware and responsive product of his day, and why should it be seen as monumental?

Naess likes to see himself as a “philosopher of life.” The thought of simply being an academic philosopher—living a life of the mind—makes him restless and uneasy. For Naess, “wonder” is both the point of departure for philosophy and the focus of the enterprise. He is the philosophical equivalent of a hunter-gatherer using his wits and intuition to seek out food (for thought) in a fecund landscape. As they were for the ancient Greeks, science and philosophy are inextricably intertwined for Naess. Science, as the application of reason through empirical investigation, cannot be separated from rational reflection on the nature of reason, and vice versa. For the mature Naess, though, philosophy and science are also distinct. Philosophy is the unique realm in which we take up the deepest, most profound, and most fundamental problems. From Naess's vantage, which defines philosophy openly and discursively, the questions that have fascinated and plagued people for millennia have not changed much and they are not likely to change significantly in the future.

Naess's view of philosophy includes the traditional epistemological question “What can we know?” and the ontological question “What main kinds of things are there?” But it also includes “How do we measure?” and “How do we know?” as well as “What is the relationship between the knower and the known?”³ These are questions that are likely to vary with cultural and social circumstances, but this does not, for Naess, imply cultural relativism. By its nature, this view of philosophy runs counter to the dream of the logical empiricists; it cannot be restricted to investigations of

SERIES EDITOR'S INTRODUCTION

“fact” or “logic.” It is imbued with fundamental valuations. Being a philosopher, for Naess, is thus a deeply personal and intimate matter that requires us to engage all of our powers and experience. It should also include questions such as “What are your aims in life?” and “What’s driving you?” as well as encourage a practice of deep and open argumentation by asking repeatedly, “Why do you hold that *p*?” in order to unearth underlying premises and hypotheses. For Naess, all these questions have an empirical component. He sees it as a duty for a philosopher to extend research into the creation and use of empirical methods to address these aspects, unless these questions can be adequately addressed by an existing empirical science, in which case it is fine for a philosopher to perform research here, but it no longer constitutes a *duty*.

In Naess’s view, philosophy is ultimately concerned with how *we*, through our experiences, perceive the world, the world’s relation to ourselves, and the basic features of the condition of people. It is the realm in which we pose sophisticated questions to address perennial problems, probe them from different angles (in Naess’s case, from as many angles as possible), and test and apply the insights to real life—to what we do and decide every day. Its purpose is not to arrive at definitive answers. The purpose of philosophy, rather, is to help us understand what *we* believe in from our innermost perspective, expand this perspective continually, and facilitate communication—so that we might contribute toward improving the state of affairs of the world.

While initially attracted to Bergson’s *les données immédiates de la conscience* (the immediate data of consciousness), Naess grew disenchanted when he recognized that one becomes lodged in an endless circular loop and never exits consciousness. Naess clearly believes that the unexamined life is not worth living (his life is a testament to Socrates’ edict), but he appreciates that disembodied, introspective examination comes at great peril. A mind-centered focus on “examination”—where subjects exist separately from objects, theory is isolated from praxis, and knowledge is decoupled from wisdom—very quickly degenerates into meaninglessness. Worse yet, separating people from and raising people above nature and the coevolutionary process that created us—and provides for our sustenance—can be inimical to life and the evolutionary process.

Nature, that which is, the reality of the pre-Socratics, is Naess’s philosophical palette, not the “world” of his own consciousness as has become

the norm with so many contemporary philosophers since Descartes. Popper and others posit the existence of three worlds that correspond to the development of our commonsense view of reality. World I is the physical world, the "external world," the world of our sensory impressions. World II is the world of all conscious experience, the psychological world of the "immediately given," which incorporates our feelings and intentions. World III emphasizes the logical content of reality. Naess finds these multiple views of reality unconvincing and potentially dangerous. With a worldview inspired by Spinoza's *Ethics*, he is fundamentally opposed to the notion of multiple worlds.

Naess's mature philosophical approach and contributions are shaped by full engagement with a relational reality, in which no firm subject/object, substance/property, universal/particular, fact/value dualities exist. John Muir's famous, deceptively simple aphorism sets the stage: "When we try to pick out anything by itself, we find it hitched to everything else in the universe." Reality as we experience it, according to Naess, is a dynamic, multilayered manifold of hierarchically related gestalts—of which we are always a part. It is the opposite of atomism. Contrary to the dominant, Western way of viewing reality, there are no extrinsically connected discrete objects or "things in themselves" in the sense of Kant's *Ding an sich*. With Naess's "gestalt ontology," there is no dualistic "I" standing outside of reality looking in. Living beings, individuals in the sense of Spinoza's modes, are spatiotemporal manifestations of "one substance," nature or reality. As Naess points out in *Freedom, Emotion, and Self-Subsistence* (SWAN VI), Spinoza's medieval terminology of substance, mode, attribute, God, and Nature is dispensable. In addition, Naess goes on to characterize "living beings" broadly to include individual organisms as well as ecosystems, rivers, mountains, and possibly Earth (Gaia).

Naess's view of reality calls for a gestalt shift. His gestalt ontology does not stop with gestalt psychology's simple notion of holism, where the whole is more than the sum of the parts. It goes on to add that the internally related subordinate gestalts are themselves more than mere parts. There are no parts as parts or wholes as wholes; higher-order wholes are not reducible to lower-order wholes. The concrete contents of reality have gestalt character. For Naess, we experience reality spontaneously and our experience of the world is made up of gestalts. "[This] is the world we experience. Nothing is more real."⁴ People create abstract structures to reflect

SERIES EDITOR'S INTRODUCTION

on or analyze spontaneous experiences and their structure; they are the interrelations between spontaneous experiences. Mind and body are mental contrivances and conveniences—abstract structures in Naess's parlance—for helping us to describe, model, or understand certain states of affairs. They are not the contents of reality. Only individual occurrences of spontaneous experience make up the concrete contents of reality.

What are the consequences of Naess's "ontological realism" as expressed in the form of gestalt ontology? First, living organisms have different levels of access to reality, based on their capacities, experiences, and backgrounds. This implication of "reality is one" plays a central role in the mature Naess's approach to philosophy of science. One of his main thrusts is to undermine the claim that the exact physical sciences show all that is, that they have a privileged view of reality. In his view, science creates extremely abstract structures of what is real, but those structures do not actually *describe* any of reality's concrete contents (descriptions are themselves normative). Jakob von Uexküll, the famous ethologist of the early twentieth century, whom Naess read closely in his youth, helps clarify this notion. "As the spider spins its threads, every subject spins his relations to certain characteristics of the things around him, and weaves them into a firm web which carries his existence."⁵

Different people experience reality differently, yet we often, incorrectly, speak of *different realities* as if they existed. By the same token, identical accounts of reality in no way imply verification of that view by correspondence; from Naess's perspective, such accounts by themselves are merely a sign of cultural poverty. "God" could have created the Earth and life 6,000 years ago, but the evidence to support this case is thin and the evidence to support evolution is stronger, in part because biological science and paleontology generally employ a greater level of depth of intention and thus aspire to maintain higher standards for the evaluation of evidence. Radical pluralism and scientific possibilism do not imply scientific or ethical relativism.

There are at least four other key implications of Naess's gestalt ontology. First, the existence of one, interdependent reality tends to curb solipsism. Second, the world we live in spontaneously can no longer be characterized as merely subjective. Expressions such as "the social construction of nature" become oxymoronic. Third, individual organisms exist as knots in a biospherical web or net. Reality is not anthropocentric; it is not particular

to humans. Fourth, humanity can no longer justifiably be seen in opposition to a separate object—nature. This insight tends to temper any “natural” tendencies toward anthropocentrism. As with Leopold’s Land Ethic, people become plain members and citizens of the biotic community, albeit ones with unique powers and proclivities and thus special responsibilities. We are all individual beings, yet we vary in the extent to which we are integrated into the whole.

Humans are massively altering the gestalt character of reality, diminishing it, making it less complex. We do this, Naess argues, without necessarily recognizing we are doing it or the extent to which we are doing it. Thus, we are unable to evaluate the tradeoffs of making such decisions. Naess argues that we generally act simply according to how we “see” reality, but there are aspects of reality that may not be available to us. These aspects are no less there because they are currently unavailable to us, yet they can be destroyed very easily. Sometimes we also confuse our abstract structures of reality (models, data, concepts, etc.) with the contents of reality and vastly underestimate the complexity of internal relations between gestalts, leading ourselves to believe, incorrectly, that higher-order wholes can be reduced to lower-order wholes. It is Naess’s hope that by embracing gestalt ontology, we are encouraged to cultivate our opportunities and faculties for experiencing reality more fully—for experiencing more complex, higher-order gestalts. It is also his hope that we will openly and more carefully consider, in advance, how a proposed research program, action, or decision might affect other peoples’ (or other life-forms’) opportunities for rich spontaneous experiences (consider, for example, the possible impacts of ostensibly beneficial research on nuclear fission or molecular biology). In the end, however, we should remember Naess’s own caution—his description of gestalt ontology is itself an abstract structure. As Naess says, “For me reality has always been something slippery to handle. I seem to grasp it firmly, but like an eel, or even a small lively trout in shallow water, firmness of grasp does not guarantee against escape.”⁶ But does reality really have gestalt character?

Truth—as in *the* truth—is not a defensible notion for Naess. For too many academic philosophers, wonder has been extinguished and replaced by a belief that definitive answers have been found, that the original, initially vexing questions can be laid to rest. Naess is under no such illusion. He views humans as essentially fallible and he sees this domain of fallibility

SERIES EDITOR'S INTRODUCTION

as extending to mathematics and formal logic. This may be why he so freely returns to previously explored material (sometimes just after writing it) and looks at it afresh, with new and frequently competing and even conflicting insights. For Naess, truth is something we seek continually without expecting or believing that it can be found. He seeks peace of mind (*ataraxia*) by suspending judgment (*epoché*). While necessity requires him to take firm positions in life, he often resists taking such positions in his written philosophy. Having reached a general state of mental suspense (*isothenia*), he prefers, as a mature sceptic, anticipating his own tendency to come up with counterarguments and counter-counterarguments, to suggest alternative paths, inspire new ways of looking at things, and foster informed, open-minded debate. This *zetetic* inclination, although nascent in many of his earlier works, was made explicit and became a central theme in his philosophical writings in the 1960s.

For Naess, passivity has no place in philosophy or life. In his famous debate with Sir Alfred Ayer, Naess defines Spinoza's *amor intellectualis* as a "kind of loving attitude towards what you have insight into, while considering it in an extremely wide perspective."⁷ For the mature Naess, *amor intellectualis* involves using his technical and intellectual training to articulate, in direct and forceful ways, his attitudes and evaluations on matters of practical consequence. Like Spinoza and Gandhi, Naess is concerned with human salvation in this world, but Naess, with his concept of "wide-identification," expands this concern to both humankind's relationship to life in general and the self-realization of all life-forms for their own sake. Whether it be understanding how lay people conceptualize truth or experts characterize democracy; considering how our approach to science not only shapes how we do science, but the nature of scientific outcomes too; using philosophy to improve practical communication; facilitating thoughtful debate on the potential dangers of Norway joining the European Union; or discussing the ethics of climbing, the meanings of sustainable development, or distinctions between different approaches for addressing the ecological crisis, Naess seamlessly connects philosophical questioning to activeness in relation to the questions.

Naess's philosophical career can be seen, in one sense, as an attempt to bridge C. P. Snow's two cultures. Believing that the central questions of philosophy are here to stay, he has developed his philosophy over seventy years in part through his effort to relate these questions to the issues of his

rapidly changing, trying, and tumultuous era. Naess's lifelong commitment to integrate interests in nature, science, and logic is evidenced by the mature Naess's championing of philosophical approaches in which both metaphysics and science contribute to all-embracing systems of thought. This approach is particularly prominent in Naess's development of normative systems theory, a strategy for promoting systematic reflection on premises and conclusions. Recognizing that all philosophical questioning must stop somewhere, Naess calls the essential intuitions that serve as bedrock assumptions for our total views, ultimate norms or ultimate premises. Further, recognizing that our philosophical conclusions as well as our lifestyles and everyday actions often appear inconsistent with these ultimate premises, Naess has developed a strategy for using premise-conclusion strings to help identify potential norm conflicts as well as to help assess whether potential agreements and disagreements are real or pseudo. Use of this technique figures prominently in Naess's approach for improving communication, in his approach for exploring both the philosophical basis for Gandhi's *satyāgraha* (active nonviolent resistance) and the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," as well as in his own Ecosophy T.⁸

With regard to total views—broad philosophical systems like Spinoza's, which attempt to communicate our deepest insights and communicate views of life—Naess argues that although the existence of complete, explicit total views is absurd, it is equally absurd to presume to criticize a total view without adopting one (at least implicitly). After relinquishing the possibility of creating a consistent empirical theory of knowledge, Naess came to believe that any theory of knowledge presupposes all major philosophical disciplines, at least on the metalevel. One cannot have a theory of knowledge without presuming a particular reality, at least implicitly, and this necessitates having an ontology, metaphysics, ethics, and so on. This has practical consequences too. We never simply act solely as a philosophy professor who specializes in logic or ethics; we are always, at least partly, mother, daughter, lover, scientist, . . . , and philosopher. If we accept the premise "For every decision we, explicitly or implicitly, take all things into consideration," then the notion of total views or total normative systems can be seen as very "useful fictions," which, if articulated, might help us to improve decision making.

Naess is careful to point out that he sees his own total view and others

SERIES EDITOR'S INTRODUCTION

as fragmentary and constantly evolving—ever “on the way.” Moreover, even if we could have a completely formed and integrated total view, we could not count on being able to articulate it. There will always be a tension between the Spinozistic goal of clarity and the pragmatic reality that in this world we can never wait until all the facts are in. None of these issues, however, justifies abdicating our responsibility to try to articulate our own total views. The mature Naess is a radical pluralist. He believes in defending coherent systems, without claiming that their relation to reality is definitive. While he is committed to the importance of models and systems, he is opposed to the idea that there could or should be a definite worldview. Naess’s hope is that there will be no definite scientific worldview in the future.

No Western philosopher since Descartes—except perhaps Spinoza, who has also been a primary inspiration for Naess—has had the potential to help us drastically reshape our relationship to each other and life in general: not by spelling out *a* clear and coherent total system—to be taken as *the* truth—but by challenging us to articulate our fragmentary total views and connect the abstract problems of philosophy to issues of contemporary social and political conflict. In Naess’s view, “[t]he full meaning of a theory can only reveal itself in practice, and practice is blind without theory.”⁹ To be a philosopher of life, one must embrace both theory and practice and engage them in dance.

In Norway, Arne Naess is regarded as a national treasure, a seeker and a seer, a “minor prophet,” in his own words. His radical pluralism and endorsement of diversity are demonstrated by his complex character. He has a proclivity for being aloof and charming, somber and joyful, accountable and carefree, arrogant and modest, slippery and precise. In a world of contradictions—breathtaking beauty *and* ineffable squalor and suffering—Naess is no exception. He is an antiguru guru. He strives for high levels of consistency and integration in his philosophy but accepts that in his personal life he cannot live up to his philosophical systems’ requirements. He strives for definiteness of intention, yet he appreciates vagueness and eschews dogma, refusing to be pinned down to a particular viewpoint or placed in a particular philosophical camp. This stance is further supported by his sometimes maddening tendency to revise, revise, and re-revise. As a consequence, one cannot go to any of his books or articles and find the “definitive” Arne Naess. He is a

troublemaker too, but the kind of troublemaker people want to have around because he challenges orthodoxies with an elfin irreverence. Naess stands out because his frequently outlandish and controversial views are felt deeply, reasoned carefully, and conveyed playfully.

Naess has had a profound influence on Norwegian academic life and the society as a whole. From 1939 to 1954 he was Norway's only professor of philosophy. He was chiefly responsible for organizing courses for the *examen philosophicum*, introductory examinations in logic, methodology, and history of philosophy that an entire generation of undergraduates (roughly 100,000 people) were required to take, regardless of their disciplinary focus. His unique paradigm of inquiry—emphasizing open-mindedness, empirical analysis, pluralism, a thorough grounding in philosophy and the history of ideas, and a vital concern for contemporary problems—is credited with shaping the intellectual fabric of postwar Norway. At a press conference for Naess's eightieth birthday, the Norwegian Minister of Education testified to the significance of the Norwegian version of Naess's *Communication and Argument*, one of the primary texts for the *examen philosophicum*. "We have all read it. We *still* cheat in argumentation, but now with feelings of guilt."¹⁰

Naess is also credited with rekindling the study of philosophy in Norway and with forming the Oslo school of philosophy. The section on Scandinavian philosophy in *The Encyclopedia of Philosophy* elaborates:¹¹

The philosophical milieu in Norway today [circa 1967] is determined by an internationally known and original philosopher. . . . Arne Naess . . . is the originator of a radical type of empirical semantics and the leader of the so-called Oslo group. . . . The empirical methods applied by the Oslo group employ carefully worked-out questionnaires. By the help of such questionnaires and by teamwork, philosophers of the Oslo group have carried out investigations of such expressions as "truth," "democracy," and "private enterprise." . . . If it is correct that Norwegian philosophy has had a dead period,¹² it is equally correct to assert that, primarily because of Arne Naess, Norwegian philosophy is now in the middle of a period of life and growth.

When asked to comment on this passage, Naess was emphatic about inserting an addendum to the last sentence.¹³ He was proud to convey that contemporary Norwegian philosophers pursue a wide variety of directions and employ a diversity of approaches, many independent of Naess's own line. This point is borne out by the more than forty-four permanent teaching positions currently at the University of Oslo's Institute of Philosophy

SERIES EDITOR'S INTRODUCTION

and the broad spectrum of approaches these philosophers pursue, from the analytic tradition to phenomenology and from existentialism to hermeneutics. As one of Naess's successors, Alastair Hannay, in his section on Norwegian philosophy in the *Oxford Companion to Philosophy*, has commented, "Norway enjoys a varied and vigorous philosophical life. . . . Philosophy's place in Norwegian academic life, as in the society at large, is due in large measure to Naess."¹⁴

The reach of Naess's contributions to philosophy and social research extends well beyond Norway. Significant international recognition has also come his way for these contributions. He has received the Peer Gynt Prize awarded by the Norwegian Parliament (2004), the Nature and Environment Prize from the Nordic Council (2002), the Nordic Prize from the Swedish Academy (1996), the Mahatma Gandhi Prize for Non-violent Peace (1994), and the Sonning Prize for contributions to European culture—Denmark's version of the Nobel Prize (1977). He has even been honored by five festschrifts, one each for the occasions of his seventieth, eightieth, and eighty-second birthdays and two for his eighty-fifth birthday.¹⁵ He is the founding editor of the influential journal, *Inquiry*, created to promote collaboration between philosophers and social scientists. He is also a renowned mountaineer and climber, an occasional nonviolent political activist, and father of the deep ecology movement. His social concern, sense of wonder, and trickster nature have all contributed to his success at numerous academic posts around the world—preferably near mountains or deserts—from Berkeley to Jerusalem and Helsinki to Hangzhou. He is, to this day, still a frequent international speaker.

Even with this high level of accomplishment, the significance of his work as a whole—as a gestalt—has yet to receive broad-scale appreciation outside of Scandinavia. There are many explanations for this situation.

The overarching reason has likely been the general inaccessibility of his oeuvre. This inaccessibility has many facets. Naess has been incredibly prolific, producing over four hundred publications, more than thirty of which are books. These publications span topics from argumentation theory to zeteticism, with adventures along the way at such seemingly incongruous destinations as climbing ethics, cultural anthropology, and deep ecology. His range of topics—in abundance, breadth, and depth—is trying, at best, for our increasingly compartmentalized and specialized academic communities.

In addition, the bulk of his most significant works have been out of

SERIES EDITOR'S INTRODUCTION

print for quite some time. Many of the earlier editions of the books were edited poorly and documented sparsely. A significant portion of his important articles and book chapters appears in obscure or difficult-to-find books and journals, and much of his work has remained unpublished (at least two hundred papers and several book-length manuscripts). Naess's main works appear in three primary languages, German, Norwegian, and English, although he has also written in Danish, Swedish, and French. Finally, Naess's prose can be dense and opaque, if not downright confusing. Although this trait is by no means unusual for a philosopher, when blended with Naess's appreciation for vagueness and ambiguity, his aversion to authoritative stances, and his tendency to revisit topics by reconsidering earlier viewpoints, the already high entrance fee can become prohibitive.

The boundless range of Naess's interests and the general inaccessibility of his entire oeuvre have led some scholars to view him rather pejoratively as a dilettante. Some of these critics view him as flitting from one area of interest to another, not mining any to its logical conclusion; some see him as throwing away a great talent in logic; some view his social research, especially his work with questionnaires on lay people's and experts' perceptions of philosophical concepts and his use of statistics, as outside the realm of serious, professional philosophy; and still others see him as inappropriately conjoining his philosophy with activism. His breadth has even led a few of the more extreme critics to dismiss his work out of hand. Although some of the criticisms detailed above do have merit, in my view Naess gives the dilettante a good name.

To address this range of concerns, the *Selected Works* project was conceived. The project was the brainchild of Douglas Tompkins. "Miracle Doug," as Arne refers to him, is the founder of the Foundation for Deep Ecology and is himself a renowned climber and kayaker in addition to being a wildlands philanthropist who has helped protect immense tracts of land in Chile and Argentina, some as large as Yosemite. The *Selected Works* would have simply remained a "great idea" without Doug's generosity and support. The project was initiated in 1994 and commenced editorial work in 1996 under my direction.

In the introduction to his *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, and Sartre* (1968), Naess decries the condition whereby the philosophical life of an individual is set by the local philosophical scene, by provincial biases, or by what is easily accessible.¹⁶ Such accidents of envi-

SERIES EDITOR'S INTRODUCTION

ronment should not, in Naess's view, play a pivotal role in shaping a budding philosopher's development. I see the *Selected Works*, at least in part, as a response to this predicament.

The purpose of the *Selected Works* is to bring—for the first time—the full scope of Naess's philosophical contributions to the English-language audience in one collection of highly readable and meticulously edited volumes that adhere to the highest standards of contemporary academic philosophical publishing. The *Selected Works* is, however, by no means exhaustive; it is not a collected works.¹⁷ We have simply aspired through careful selection to offer a representative and relatively expansive collection of Naess's principal writings. As such, the *Selected Works* is the definitive repository of Naess's oeuvre, chronicling the development and progression of his thinking for scholars, students, and critics alike.

In the remainder of this essay, I attempt to sketch briefly one possible version of an intellectual biography for Arne Naess. I endeavor to trace some key influences on Naess's philosophical development, discuss the evolution of his philosophical outlook, and touch on the relevance and significance of each volume in the *Selected Works*. I close with a short note on our editorial approach.

From Scientism to Wisdom: Toward a Philosophy of Life

The philosophic researcher should be task-minded, not discipline-minded, and should follow his questions wherever they lead.

Arne Naess, "Norway"

Arne Dekke Eide Naess was born in 1912 in the dining room of a large house with a wild, expansive garden. The house was on the outskirts of Oslo in Slemdal, a short walk from where Naess lives today. Arne was the unplanned fourth child of a wealthy family from Bergen. Before he was a year old, his father, who was ill with cancer, had died. Overwhelmed, his mother, Christine, entrusted little Arne to the family's governess. This is where his first memories begin.

Arne speaks of Mina, his governess, endearingly. She is described as satisfying little Arne's every wish, be it procuring live flies for his bath or bringing a trunk filled with bottles on a family trip so that he could continue his water-play experiments. Sometime before Arne was four, Christine dismissed Mina, ostensibly for spoiling Arne too much. This initiated a deep

SERIES EDITOR'S INTRODUCTION

rift between Arne and his mother, which was never to be mended. It also set in place a sense of loss, alienation, and resistance to emotion that profoundly influenced Naess's early personal and philosophical development.

Significantly later, after an intensive six-day-a-week, fourteen-month psychoanalysis with Freud's noted collaborator Dr. Edvard Hitschmann, Naess came to understand his impenetrable shell that keeps others at arm's length (*Panzercharakter*, in Freudian terms) as resulting from a reaction to his mother's unreliability and emotional hysteria. His effort to keep his mother at a distance morphed into a general aloofness and distancing. The adolescent Arne began to favor an "objective," bureaucratic approach to language. He saw art, music, and poetry as being seduced by emotion, by beauty and form, but viewed science and philosophy as realms from which such emotions should be banished. This prejudice would take decades to overthrow. At this time he also developed a single-mindedness and resistance to inconvenience and pain that to this day make it easier for him to concentrate and focus. As Hitschmann pointed out, however, this inward turn has a flip side, a certain self-destructive or masochistic bent that was later to plague him, particularly in his relationships with women and his children.

Much of Arne's early childhood was spent at the seashore, and this is the period in which his interest in nature and experimentation began to flourish. Feeling somewhat distanced in his relations with people, he identified with nature, especially little sea creatures. He waded in shallow water for hours, inventing experiments to test nascent hypotheses about the behavior of small sole, tiny translucent shrimp, and crabs. He describes these experiments as engendering an early enthusiasm for diversity and a tendency to suspend judgment on the nobility or status of different beings. He loved these creatures for their unique qualities and their amusing adaptations and limitations. They inspired a certain egalitarianism, which took hold and later influenced his philosophical approach in profound ways.

Young Arne was restless. He had an early penchant for "collecting" and organizing large groups of numbers, stones, and stamps. He started climbing trees in the family's little "wilderness" before he was five and soon progressed to big firs and spruces. He found that he enjoyed being able to watch people from above. Arne outgrew trees fast. His desire for perspective and the opportunity to survey broad areas was rapidly transferred to mountains. At the age of five, he began going to his mother's small moun-

SERIES EDITOR'S INTRODUCTION

tain cottage in the town of Ustaoset, high in the Hardangervidda between Oslo and Bergen. By the age of eight, he had adopted Hallingskarvet, a bread-loaf-shaped mountain about three and a half hours' walk from Ustaoset, as his surrogate father. In his teenage years, this obsession for expansive perspectives translated into a lifelong passion for mountaineering. When Naess was sixteen or seventeen he climbed the 106 tallest mountains in Norway. It was around this time that he was first introduced to Spinoza's *Ethics* by a Norwegian Supreme Court justice that he met in the mountains. Naess's desire for a broad and open perspective, for seeing things in totalities (god's-eye view), translated to his studies. Young Naess read widely in economics (especially value theory), science, philosophy, history of philosophy, and the Earth's biological history.¹⁸ This commitment to cultivate an ever-expanding perspective would later potently influence his approach to philosophy.

Arne's youth was spent captivated by piano, study, and mountains. His decade-older brothers took it upon themselves to toughen up their timid younger brother, as well as introduce him to the ways of the world and scholarship. When Arne was only eight, his eldest brother, Ragnar, left for America to study for a Ph.D. in chemistry at MIT. Ragnar later went on to receive one of the Harvard Business School's first degrees and became a successful stockbroker in the United States. Erling studied economics and went on to create an international shipping empire; he became famous for his assistance to the Norwegian government-in-exile during the Nazi occupation. His sister, Kiki, married a German doctor and after the Second World War returned to Norway to become a physical therapist. From Kiki he learned the power and significance of offering encouragement to others. During his early years and well into adulthood, Arne's tight-knit relationship with his siblings provided security and support for him to "find his own way"—*sva mārga*, to use one of his favorite Sanskrit terms. Although he tended not to seek their financial assistance, his wealthy and generous brothers offered a sense of comfort, safety, and the occasional extravagance, which in later life made it easier for him to live his bon mot, "simple means, rich ends."

Naess studied philosophy, mathematics, and astronomy at the University of Oslo. At nineteen, after completing the equivalent of an undergraduate degree, he left Oslo to continue his studies in Paris. Naess was put off by the adoration Bergson received in Paris, but ultimately left to seek

broader vantage points, cheaper living, and better climbing opportunities. After completing two master's theses at twenty-one, one exploring discussion about the concept of truth and the other exploring the use of behavioral psychological principles to judge truth validity, Naess left Oslo again, this time for Vienna. In Vienna he took master classes in piano, where, following his trickster nature and as a response to the strict taskmaster Fuchs, he "learned" new material. When he ran out of pieces he had long since mastered, he quit. Thinking that it was necessary for philosophers to have high levels of self-knowledge, he underwent intensive psychoanalysis with Dr. Edvard Hitschmann. As a part of that process he assisted with the treatment of patients in a psychiatric hospital and developed tremendous empathy for the suffering of humankind. While in Vienna, he was also warmly welcomed at the famous Schlick seminar.

The logical empiricists' friendly, equiminded approach to discussion made a great impression on Naess, but he was not equally affected by their ideas.¹⁹ The young Arne was impressed by the preciseness, empirical nature, and lack of emotion in science—he wanted to practice philosophy with a scientific bent and he wanted to test philosophical hypotheses with experiments. He was already interested in perennial philosophical problems and did not believe that most of them were ultimately pseudoproblems that could be solved by investigating inconsistencies in language. His most significant philosophical issue with the logical empiricists was not that they were empirical, although he believed they were misguided in thinking that any philosophical problem could be wholly empirical, but that they were ultimately antiempirical in their belief that a logical grammar of language was more suitable for investigating the use of terms than statistical analysis of their actual use. Naess's detailed critique of the logical empiricists' position and reflections on his personal experiences attending the Schlick seminar appear in volume VIII. In this critique, Naess expresses a concern that in their interpretation of terms, many philosophers (not just the logical empiricists) were artificially constricting the range of possible interpretations and thus unintentionally reducing potential insights regarding the diversity of tenable positions on problems of vital concern. This perspective presaged his later views, particularly those expressed in *Interpretation and Preciseness* (SWAN I), and his later approach to cultural anthropology and philosophy of science. Naess sums up his general perspective on the state of philosophy at the time with the following remark: "The

turn of (Western) philosophy in [the twentieth century] towards language rather than cosmos, towards logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind-alley."²⁰

While in Vienna for fourteen months in 1934 and 1935, Naess made final revisions to his doctoral thesis, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior).²¹ Although Naess drew inspiration early on from Russell and Whitehead, his doctoral thesis can be seen, in part, as support of the American Pragmatists (James and Dewey) in opposition to Russell and early Wittgenstein. According to Dewey, the main purpose of his philosophical writings was "to reintegrate human knowledge and activity in the general framework of reality and natural processes."²² Naess did just this by creating a radical and unique approach for exploring how high science is performed, a sort of science of science. At this point, Naess believed it was possible to use such an approach to obtain a complete account of all science within one system. Inspired by the ethologist Uexküll's "special biology" (*Umweltforschung*), Tolman's "objective" behavioral psychology ("molar" behaviorism), and the cultural anthropologist Malinowski's work on speech and nonverbal behavior, Naess took on the standpoint of a neutral, nonparticipant spectator and outlined a program for an empirical metascience of science, an ethological approach to epistemology of science.

Naess used the idea of a dispassionate visitor from another solar system coming to study Earth-based scientists to demonstrate the possibility of completely describing both the activity of researchers and the contents of knowledge without drawing on the subjective models that governed traditional epistemology and presupposed knowing subjects or minds. The idea was to study or rather "witness" science similar to the way experimental psychologists study rats, but without falling into the trap of imposing their own experience of reality and their preexisting conceptual models of reality ("maze epistemology"), or their scientific pretensions. In the view described in *Erkenntnis*, knowledge is cognition—it is an activity with intention—and this helps to dismantle the subjectivist dualism between the content of knowledge and the activity of research. Naess's interest was in describing these patterns of research activity. He argued that the *terminology* associated with scientific activity—which is bound to the subjective-reality model—changes in leaps and bounds, not the *patterns of research activity*, which are in constant, but gradual, flux. With this argument that

change in science happens gradually, by generalization and differentiation, Naess foreshadowed his response to Kuhn well before *The Structure of Scientific Revolutions* was published in 1962.

With *Erkenntnis*, Naess also anticipated ideas that later became prominent in linguistic philosophy, such as the importance of ordinary language over formal systems and the importance of using observation of contrasts and discriminations to build up understanding of systems. In the end, presaging his own radical pluralism to come, Naess seems to relax his early position on the importance and possibility of creating a metascience of science from the “far outside” and ultimately comes to view subjective and behavioral models as two different point-of-departure formulations in an indefinite plurality of equally valid approaches for a metascience of science. This refined perspective is taken up in Naess’s 1965 article “Science as behavior” (in SWAN IX), which returns to the prospects and limitations of creating a behavioral metascience to study the scientific enterprise, but this time from the “near outside.”

At age twenty-four, after receiving his Ph.D. from the University of Oslo for his work on science as behavior, Naess returned to his interest in the problem of truth. A particular concern was the inadequacy of philosophers’ intuitive methods for capturing how lay people conceived and used the term *true*. In 1937 and 1938 he developed and tested an empirical approach for using questionnaires and statistical analysis to investigate non-philosophers “commonsense” views on the notion of truth. He then related these notions to philosophers’ theories of truth. Naess found an amazing diversity of views among the amateurs. He also found that their views, although typically devoid of philosophical pretensions, generally covered the views represented by professional philosophers. This work elicited substantial controversy, most of which came from philosophers who viewed it as undignified to use questionnaires and statistics to investigate one of the great problems of humanity. Naess’s results were published as “*Truth as Conceived by Those Who Are Not Professional Philosophers* (1938). A summary of this work is presented in Naess’s “Common Sense and Truth” (in SWAN VIII). Naess’s continued application and refinement of these techniques would evolve into empirical semantics.

In 1937 Naess fortified his lifelong fascination with the arctic climate Hallingskarvet by building Tvergastein, his now-famous rustic and remote hut, at its base, a three-and-a-half-hour trek from the train station at Us-

SERIES EDITOR'S INTRODUCTION

taoset. He outfitted the hut with Rube Goldberg oil lamps that also served as stoves for warming tea and with an eclectic library of teach-yourself language manuals, Sanskrit-English dictionaries, astronomical and wildlife field guides, novels by Dostoyevsky and Ibsen, letters of Spinoza, and a complete philosophy library. Following his passion for amateur science he also created “institutes” of petrology, chemistry, zoology, hydrology, and botany at Tvergastein. Naess has written the bulk of his work at Tvergastein and spent the equivalent of about twelve of his ninety-two years living there. The enormous open views at Tvergastein afforded Naess the distance and perspective he so craved while insulating him from philosophic fashion and dogma. Here he had the luxury, freedom, and good fortune to pursue his own interests free from the banalities and distractions of academic life. After completing what is now Tvergastein's main room, Naess went on to perform postdoctoral research at Berkeley (1938–39) with the pioneer of empirical psychology, E. C. Tolman. At Berkeley, he went from studying the behavior of rats faced with many possible alternatives to studying the behavior of the scientists studying the rats.

Naess returned to Oslo in 1939 to be appointed to the University of Oslo's Chair of Philosophy at the age of twenty-seven. On April 9, 1940, German forces invaded Norway; it would remain under Nazi rule for the next five years. This was a harrowing time for academics throughout Europe. Arne tried to maintain his unruffledness, pouring himself into research and curricular reform initiatives intended to widen and expand the perspective of university undergraduates. He tried to stay at Tvergastein often, and this afforded him some peace and solace in a world of great tension. Before long, however, even he was drawn into the resistance movement. In the fall of 1943 he played a central role in foiling a Nazi attempt to deport University of Oslo students to concentration camps for “reeducation.” The University was subsequently closed and Naess became even more committed to the resistance movement and his research. By this time he had developed great admiration for Gandhi's catalytic 1930 *satyāgraha* campaign, the march to Dandi in protest of the British salt tax. Naess was greatly impressed with Gandhi's idea of trying to meet one's opponent in a manner that would calm passions and facilitate truthful communication. He thought such an approach could have had a significant effect on quenching the Nazi expansion, *if* the necessary infrastructure to support *satyāgraha* had been created in European countries. After the war,

Naess used these insights in his efforts to bring together suspected torturers and the families of torture victims to gain a sense of closure on the fate of their loved ones—and to avoid having the “traitors” subjected to equally horrid persecution. In 1948 Naess was invited to be the scientific leader of a new UNESCO project created to explore ideological controversies between the East and the West. He was soon off to Paris again, this time to pursue his interest in using philosophy to address questions of social and political importance.

The Cold War was a tinderbox and two core ideological conflicts revolved around use of the terms *democracy* and *freedom*. Naess was asked to address both but countered that UNESCO's requirement that he deliver a report within one year made it essential for him to consider *democracy* first. His goals were to clarify what people mean when they use the term *democracy* and to understand the causes of ambiguity and confusion that result from its use. After an extensive literature review, which chronicled historical usage of the term, Naess and his assistant, Stein Rokkan, prepared a thirty-question survey that was distributed to almost 600 international experts in the fields of philosophy, law, history, political science, sociology, economics, communications, and logic. Naess used the roughly 100 replies to create an empirical study of “agreements” and “disagreements.” The study demonstrated *democracy's* richness, diversity, and multiplicity of meanings and thus undermined its misuse in both the East and the West. This incited detractors from every ideology, who roundly criticized the resulting report, *Democracy in a World of Tensions*, which according to Naess “was promptly sold out and never reprinted by UNESCO due to the politically dangerous character of its items.”²³ Naess's “Analytical Survey of Agreements and Disagreements,” along with two other pieces on ideological convictions and rationality, appears in SWAN IX.

The UNESCO democracy study was the first and last international, large-scale application of Naess's empirical semantics approach. He was originally interested in doing another study on “cultural diversity,” but neither this nor the “freedom” study came to fruition. Naess learned—much to his chagrin, and as his superiors had warned—that UNESCO was a place for writing reports; it was no place for conducting research. Naess's frustration with the UNESCO experience and his wanderlust for the perspective of mountains led him to daydream first, and then to “pursue non-essentials”:²⁴

SERIES EDITOR'S INTRODUCTION

The arguments against abandoning the imaginary joys of the Himalayas for an actual expedition seemed strong to me, and so they still do. But in the autumn of 1948 the longing for the mountains pushed aside all sensible considerations. For the first time since I was twelve years old, I had to do without a summer holiday in the mountains. The safety valve guarding one against exaggerated climbing expeditions was thus removed. Added to this came the great disappointment in my own work. Lured by UNESCO's plans of philosophical research into international ideological conflicts, I had been tied up in Paris for nine months. Such large-scale extravagant schemes prove, however, impracticable. Too much nationalism and too little belief in research prevented UNESCO from getting the number of nations to subscribe to such long term schemes. By the way of compensation, I indulged at night in delightful trips to the Alps. As the situation got worse, this was, however, not sufficient compensation; the material was exhausted. Then my fantasies took me to the Caucasus. Later I had to go all the way to Persia, Afghanistan, Hindu Kush and India, and so I was committed.²⁵

Although Naess's research interests and total view continued to evolve after 1953, the general philosophical approach of the mature Naess, outlined at the beginning of this essay, was basically in place. Naess has described his philosophical work as falling into four periods or phases. From the mid-1930s until about 1940, he focused on philosophy of science. Then until about 1953, he concentrated on empirical semantics. A short period, surrounding the publication in 1968 of his major work on the zetetic scepticism of Pyrrho, ends when, at the pinnacle of his philosophical career, he sought early retirement in 1969 to devote himself more fully to ecological issues and activism. Naess has commented that this effort to be more actively engaged in social and political conflicts reflects his desire "to live rather than function." This view adequately reflects coarse, general trends, but it fails to do justice to Naess's philosophical approach, which has him mine a larger range of topics and return to them in a helical fashion throughout his life. I would rather describe his work as falling into thematic areas that were picked up, sometimes put on ice, but returned to periodically throughout his life. Although I concur that the period after his formal retirement can be seen as emphasizing ecological philosophy and activism, the two decades between 1960 and 1980 also represent a period of considerable productivity on conventional academic philosophical topics. It was in those decades that Naess produced important work, especially, on

scientific and cultural pluralism, Gandhi and Spinoza scholarship, history of philosophy and philosophy education, and normative systems theory. He has written on a wide range of important philosophical topics even into the 1990s and beyond, during which time he produced, among other works, his *Life's Philosophy* (2002; coauthored with Per Ingvar Haukeland), introductions to the philosophy of Gandhi (2000) and Spinoza (1999), and *Introduction to General Relativity and Its Mathematics* (1998; coauthored with Øyvind Grøn).²⁶ An adequate sketch of Naess's subsequent research interests and philosophical development can be gleaned from the following brief discussion of the volumes in the *Selected Works* and the discussion, at the end, of how his earlier work figures into the evolution and exegesis of deep ecology.

Naess's best-known philosophical work is likely *Interpretation and Preciseness*, published in 1953 (SWAN I). It is an attempt to convince the world of analytical philosophy about the types of approaches that are necessary, from the standpoint of a radical empiricist, to adequately interpret terms and point-of-departure statements (T_0 statements), given the manifold of plausible interpretations. It highlights the role and potential of experience in relation to intuition and reflection by requiring that every direct or implied hypothesis regarding the actual use of terms, phrases, or sentences be testable. In addition, it responds to the ostensibly antiphilosophical sentiment in *Erkenntnis* by clarifying the function of and relationship between point-of-departure statements and precizations. In Naess's semantics, the most general statements, T_0 statements (words or sentences), are phrased in ordinary language and are intended to be philosophically neutral. T_0 statements serve as points of departure for investigations of possible interpretations. When a new interpretation of an expression eliminates some of the ambiguity of a preceding interpretation, without adding any new ambiguity, it is said to be a "precization." Thus, a sentence T_1 is more precise than a sentence T_0 when every plausible interpretation of T_1 is also a plausible interpretation of T_0 but at least one plausible interpretation of T_0 is not a plausible interpretation of T_1 . This process of using successive differentiation to better understand people's interpretations of terms, phrases, or sentences can go on almost ad infinitum; it is limited only by time, resources, imagination, and willing test subjects. With this process, however, Naess has created a formal approach for classifying different statements (interpretations) based on users' "depth of intention," the point at which they no longer, explicitly or implicitly, accept or embrace higher levels of precization. A focal point is

SERIES EDITOR'S INTRODUCTION

Naess's approach of directly employing surveys to explore systematically and empirically the meanings of terms, phrases, or sentences based on their occurrences. Naess also created a formal procedure for comparing occurrences, both interpersonal and intrapersonal, that involves performing tests for different forms of synonymy. Naess has applied his empirical semantics approach to explore the meanings of "truth," "democracy," "it is the case," "certain," "perfectly certain," and "extremely probable" (see SWAN VIII for additional details on and applications of empirical semantics).

In *Scepticism* (SWAN II), published in 1968, Naess takes on the generally accepted position that scepticism, if widely embraced, leads to the intuitively false conclusion that we cannot know anything. Naess explores the variety of historical interpretations of scepticism in light of Sextus Empiricus's outline of Pyrrhonian scepticism. Three categories of philosophical positions on the question of truth are considered: Dogmatists claim at least one truth, Academicians negate the possibility of finding any truths, and Pyrrhonists neither assert that they have found any truths nor assert the impossibility of finding one. Naess takes a sympathetic view of this last group, arguing that this form of zeteticism can represent both a viable philosophical position and a way of life that supports positive mental health. What ultimately sets this position apart is not that supporters are fundamentally opposed to making acts of assertion, to stating that "something is the case," but that they do not make such assertions with the conviction of truth. Naess also uses empirical semantics to demonstrate support for this position on rational and epistemological grounds. Distinguishing between one's philosophical view and the necessity of firm, socially responsible action in everyday life, he also responds to the common notion that this radical nondogmatism generally leads to paralysis of action. In the end, Naess argues that adopting this updated view of Pyrrhonic scepticism could lead to quite the opposite, a more open-minded approach to philosophy and life. Further elaborations on particular aspects of Naess's Pyrrhonism along with a response to Rescher's reappraisal of scepticism appear in SWAN VIII.

Which World Is the Real One? (SWAN III), which was first published in 1969 and revised in 1982, is, in part, an attempt to reinvigorate appreciation and study of the broad variety of philosophical outlooks and total views that exist in Chinese, Indian, Greek, Western, comparative, and recent philosophy. It makes use of Naess's empirical semantics, developed in *Interpretation*

and Preciseness, to argue that it is an illusion to assert that combined scientific and philosophical or “purely” philosophical syntheses of such total views can exist. Naess argues that the results of science cannot be integrated into any single world picture, in part because such attempts at synthesis are necessarily fragmentary and because valid multiplicities of syntheses exist. He also takes up the question of the comparability of total views. Such comparisons, although important, are inevitably shaky because, despite admirable aspirations for standing back to obtain a meta-perspective, real people can never totally throw off their own total views; regardless of how explicit those views may be or of how conscious of them their holders are, biases are unavoidable. We always have our own perspective to contend with. For Naess the inevitable conclusion is that pluralism is inescapable and nothing to lament. He combines these points of view with a discussion of cultural anthropology to argue for the critical importance of supporting the flourishing of rich cultural diversity. Additional articles elaborating themes related to the significance of maintaining cultural diversity and its relationship to ecological sustainability appear in SWAN X.

In *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), published in 1972, Naess suggests that scientific theories must be understood in the wider context of the plural rationalities from which they spring. Science is not autonomous. Nor can it be seen justifiably as arising independently from the general enterprise of building philosophical systems. Furthermore, the relationship of models to reality is always indirect. This volume should be seen as an effort to erode the popular misconception of science as infallible and a viable surrogate for religion, not as an attempt to build a unified theory of science within one system, which Naess had long since rejected. Because no theory can ever be either fully verified or falsified, there exists a significant freedom of choice in both modes of exploration and theories that one can tentatively adopt. The notion of “fundamental theories” is immediately called into question. As the undemonstrated (and often undemonstrable) assumptions upon which theories rest are changed, a huge multiplicity of possibilities for future theory development arises, thus possibly helping to inspire a renewed enthusiasm in science by broadening our concept of rationality and restoring the role of imagination. Articles extending or elaborating on the ideas in *The Pluralist and Possibilist Aspect of the Scientific Enterprise* appear in SWAN IX.

Naess's third book on Gandhi, *Gandhi and Group Conflict* (SWAN V),

SERIES EDITOR'S INTRODUCTION

was published in 1974. This book develops an intellectually rigorous presentation of the theory of *satyāgraha*—the way of militant nonviolent resistance—as a strategy for conflict resolution. This work is a paradigmatic example of Naess's approach to research and writing. As the eminent Norwegian social scientist and peace researcher Johan Galtung has suggested, Naess's 1955 *Gandhis Politiske Etikk* (Gandhi's political ethics)—with Galtung—and his 1965 *Gandhi and the Nuclear Age*, along with his articles that analyze or extend on Gandhi's work (see SWAN IX and X), act as exercises or drafts for this, his major work on Gandhi.²⁷ Using Gandhi's own recorded accounts, Naess explores the norms and hypotheses tacitly employed by Gandhi in his nonviolent campaigns and then uses these to create the first philosophical and logical systematization of Gandhi's approach to militant nonviolence. A careful investigation of Gandhi's two ultimate norms (as interpreted by Naess), "Seek complete self-realization" and "Seek truth," and his belief in *advaita* (nonduality), along with a consideration of their parallels to Spinoza's unity thesis, will reveal interesting insights into Naess own characterization and use of "Self-realization!" as the single ultimate norm of his Ecosophy T. Naess also considers Gandhi's approach to nonviolent conflict resolution in light of contemporary reactions against the use of nonviolence by Frantz Fanon, Malcolm X, Stokley Carmichael, C. V. Hamilton, and Sartre. He then examines Gandhi's ideas and intentions regarding group conflict in light of the ideas and intentions underlying other modern philosophies of conflict, including those of Luther, Nietzsche, Tolstoy, and Jaspers.

In *Freedom, Emotion, and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics* (SWAN VI), Naess uses symbolic logic to present a formalization and partial reconstruction of a small but important part of the *Ethics*. Spinoza's system is embedded in the seventeenth century and expressed in Medieval Latin. Two of Naess's goals are to bring empirical analysis to bear in trying to interpret and update Spinoza's system and to make Spinoza's insights more accessible and relevant to contemporary readers. To perform his reconstruction, Naess draws heavily on a small book he produced in 1962, *Equivalent Terms and Notions in Spinoza's Ethics*, which lists and discusses 243 equivalences that are directly asserted or suggested by Spinoza in the *Ethics*, according to Naess.²⁸ Accepting the transitivity of the equivalence relations as a general rule, Naess argues that a vast array of structural relations can be elucidated (many of these are often only suggested or implicitly asserted by

Spinoza). One of Naess's key conclusions is that every living thing is to some extent "in itself" and to some extent "in something else" due to the presumed gestalt nature of reality. Another is that the terms *substance*, *attribute*, *God*, *mode*, and *Nature* are "expendable"; Spinoza's basic nondualism is made clearer by Naess. A third conclusion is that *to be active* and *to understand* cannot be systematically distinguished in the *Ethics*. This notion, which has important implications for philosophy of science, is also embedded in Naess's conclusion in *Erkenntnis* that knowledge is cognition—the content of knowledge and the activity of research cannot be cleanly separated. Naess uses his analysis to explicate three main themes of Spinoza's system: the importance of a notion of uncoerced freedom (not coerced by externals), the importance of developing and acting on strong emotions to make progress in achieving higher levels of freedom, and the importance of joy that activates the complete person (as opposed to joy that simply activates part of the body or the soul). By clarifying the semantic structure of a central part of the *Ethics* with his own logical structure, Naess explains that there exists a wide variety of possible interpretations of the contents of the *Ethics*. Articles on Spinoza's determinism and its relationship to freedom, Spinoza and Māhāyana Buddhism, "Spinoza's Finite God," and other Spinoza-related topics appear in SWAN IX. Articles that explore Spinoza as an inspiration for deep ecology appear in SWAN X.

The English translation of *Communication and Argument: Elements of Applied Semantics* (SWAN VII), which was first published in 1966, is largely a popularization of the central ideas in *Interpretation and Preciseness*. The English edition is a somewhat watered-down version (no exercises) of the Norwegian edition that from 1941 to 1969 was used by nearly 100,000 university students in the *examen philosophicum*. Its purpose, to quote the *Times Literary Supplement*, is " . . .to teach people in a democratic society to think clearly, coherently, and above all responsibly." Naess's hope is that teachers use controversial examples from current events—the more emotional the better—to confront students with their own confusion and encourage them to strive for higher levels of depth of intention. The final chapter outlines six "Gandhian" rules of effective discussion, which emphasize avoiding six forms of "irrelevance in discussion."

The first two volumes of selected papers (SWAN VIII and IX) contain important material that is not covered by the preceding volumes, material that complements them, or material that builds on or reevaluates positions

SERIES EDITOR'S INTRODUCTION

taken earlier. Volume VIII includes sections on "Empirical Semantics and 'Truth,'" "Zeteticism," "Empiricism, Possibilism, and Pluralism," and "Metaphysics, Morals, and Gestalt Ontology." Volume IX includes sections on "Democracy, Ideology, and Rationality," "Philosophy of Science," "The Philosophy of Peace, Gandhian Ethics, and Communication," "Spinoza," and "Philosophical Development, Environment, and Education" (which includes an autobiographical article describing key influences in Naess's philosophical evolution, "How My Philosophy Seemed to Develop" and an interview, "Deep Ecology and Education"). A number of the especially significant articles have already been referred to, where relevant, in the discussion of Naess's philosophical evolution; other articles are discussed in the notes.

Today, Naess is, perhaps, best known for his "deep ecology" writings, the topic of *Deep Ecology of Wisdom* (SWAN X). This work began with a short unpublished paper written in 1965, "Nature ebbing out" (in SWAN X), and continues to this day. As the primary architect of deep ecology, Naess has more than seventy-five published articles and book chapters and more than sixty unpublished pieces on this topic. His only book-length discussion of deep ecology began with a short mimeograph, *Økologi og Filosofi* (Ecology and philosophy), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi, Samfunn og Livsstil* (Ecology, community, and lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. This book has not been included in the *Selected Works* because it is widely available and currently in print.

Volume X is the first comprehensive collection of Naess's work on deep ecology—it includes a broad array of articles on its history, influences, theory, development, practice, and prospects. This volume shows how deep ecology represents the integration and culmination of Naess's lifelong interests in philosophy, social research, activism, science, and nature. It demonstrates how Naess, in his explication and elaboration of deep ecology, draws extensively from both his life experience and his research on empirical semantics, scientific and cultural pluralism, Pyrrhonic scepticism, Spinozistic nondualism and activeness in relation to problems, gestalt ontology, normative systems theory, total views, and Gandhi's concepts of self-realization and nonviolent communication. Volume X also shows how Naess's approach to deep ecology has unfolded over time, with substantial emendation, in part as a response to the worsening ecological crisis, in part to answer criticisms that deep ecology was turning into a cult or religion,

and in part to address the considerable confusion and controversy that arose from his use of provocative terminology and philosophical vagueness.

Ever since he coined the term *deep ecology* with his now famous paper "The shallow and the deep, long-range ecology movement: A summary," (in SWAN X) given at the 1972 Third World Future Conference in Bucharest, Naess's central concern has been to use philosophy and philosophical thinking to help humans overcome the ecological crisis and, ultimately, to restore the Earth to a state of rich and flourishing biological and cultural diversity (see volume X). A basic premise is that some ethical norms, particularly those grounded in spontaneous experience, can be tentatively accepted as objectively valid. An example for Naess would be the statement that "Every living being has an equal right to live and flourish, *in principle*." This statement in no way denies that maintaining our existence necessitates killing living beings. Another key premise is that the human potential for caring is not static or limited—it can be both extended and deepened. The ecological crisis is embedded in an ecocultural crisis. Its resolution will necessitate cooperation and collaboration among the peace, social justice, and ecology movements.

Naess does not see himself as "inventing" deep ecology. Rather, he gave a name and a philosophical framework to a minority tradition, a nascent social movement that has been with humanity since at least Buddha, Chuang Tzu, Saint Francis of Assisi, Thoreau, John Muir, and Aldo Leopold, and is epitomized by Marjory Stoneman Douglas's 1947 *Everglades: River of Grass* and subsequent crusade to save the Everglades.²⁹ This movement finally came of age in the contemporary era after Rachel Carson's *Silent Spring*. Naess's work on "deep ecology" can be subdivided into three main thematic areas.³⁰

What I refer to as Naess's deep ecology approach (deep ecology as an ecophilosophical approach) represents his contributions to deep ecology theory—it is essentially an outline of a general philosophy of life, which draws considerable inspiration from Gandhi and Spinoza. The focal points are encouraging ultimate beliefs that support our capacity to identify with all living beings and Naess's general, pluralistic, normative systems-based strategy for assisting individuals in the process of weaving their ultimate beliefs, descriptive and prescriptive premises about the world, ecological science, and philosophy into systematic conceptual structures for relating to the world—ecologically inspired *total views* or *ecosophies*.

His work characterizing and supporting deep ecology as an international, grassroots social and political movement, along with his work enter-

SERIES EDITOR'S INTRODUCTION

ing into the fray, addressing conflicts, implications, and practical applications of the theory, falls into the realm of contributions to the “deep ecology movement.” Supporters of the deep ecology movement are not united by a commitment to deep ecology as an academic ecophilosophy (which they may not be familiar with or embrace), but by their willingness to endorse the eight-point deep ecology platform, prepared by Naess and Sessions in 1984.³¹ Finally, work discussing his personal systematization of a deep ecological total view falls into the realm of “Ecosophy T.”

Naess coined the terms *deep ecology* and *shallow ecology* in 1972 to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis. In proposing the deep/shallow contrast, he made a technical semantic distinction directed at our level of problematizing—the extent to which we can, and do, coherently and consistently trace our views, practices, and actions back to our ultimate beliefs or bedrock assumptions. Naess starts with a premise, which he has investigated empirically, that at the level of their ultimate beliefs, people generally identify with and appreciate nature. He then uses this to argue that many regrettable environmental decisions are made in a state of “philosophical stupor,” in which narrow concerns are confused with, and then substituted for, more fundamental ones.

The “shallow,” currently more influential approach to environmentalism is identified with treating the symptoms of the ecological crisis, such as pollution and resource degradation. This reform-oriented approach is grounded in technological optimism, economic growth, and scientific management, not in ultimate premises that plumb the relationship between people and nature. It thus ultimately fails to address the philosophical, social, and political roots of the ecocultural crisis.

The “deep” approach, on the other hand, while in no way discounting the exigency of addressing pollution and resource degradation, adopts a broader, long-term, more sceptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach’s proposed solutions take into consideration the nature of reality and the complexity of the problems its adherents hope to rectify. Stressing the importance of addressing the fundamental roots and coevolving causes of the ecological crisis, deep ecology posits that along with humans’ special capacities for reason and moral consciousness come special responsibilities,

particularly in relation to the flourishing of nonhuman life and the ecocultural sustainability of the planet.

The deep ecology approach calls for expanding our sphere of concern to all living beings—charismatic or dull, gargantuan or tiny, sentient or not. It acknowledges that every living being has value in itself and views the flourishing of nature and culture as fundamentally intertwined—as part of one reality. This *wide-identification* is characterized by the perception that all life is interdependent; common goals bind all living beings to the life process. In Naess's view one can arrive at wide-identification by drawing on a broad diversity of philosophical or religious ultimate premises, with roots ranging from Christian Stewardship to the Gaia Hypothesis to Naess's own ontologically inspired "Self-realization!" In its most expansive form, wide-identification is the intuition that nature's interests and our own coincide, as with Naess's "Self-realization!"—something akin to a blending of the Hindu *ātman* with a biospherical Pareto-optimality principle. Simply stated, this principle asserts that the increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other individuals or species.

By juxtaposing these two, almost caricatured perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The central premise is that society's potential to overcome the ecological crisis rests on guiding discussion and debate to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and their actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an individual's actions and his or her fundamental beliefs, while possibly engendering serious ancillary conflict along the way, will ultimately generate progress toward ecocultural sustainability.

Naess contends, as I have pointed out earlier, that humans act as if we have total views whether or not we make such structures explicit. Because our decisions regarding society and nature are guided by our total views, Naess maintains, we *should* attempt to articulate them. By making these structures explicit, we expand both our opportunities for fruitful debate and

SERIES EDITOR'S INTRODUCTION

interchange and our possibilities for creating policies that are consistent with our collective ultimate beliefs. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending "rights" to certain nonhuman life-forms or grading intrinsic value. The ontologically inspired deep ecology approach attempts to counter the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudo-rational thinking.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of "depth." In the context of deep ecology as an ecophilosophical approach, depth refers to both the general level of problematizing we employ in seeking out the underlying, co-evolving causes of the ecocultural crisis and the extent of our willingness to consider an expansive array of social and policy responses, even if they necessitate changes that constitute a radical departure from the status quo. Rather than calling for a new environmental ethic or a radical change in fundamental values, Naess's approach to ecophilosophy centers on transforming practice and policy by challenging us to develop more thoroughly reasoned, consistent, and ecologically inspired total views. This work represents a culmination of his effort to integrate reason and emotion. He has created the foundation for a new and promising human/nature relationship that positions humans as plain citizens with special abilities and unique responsibilities and nature as mentor, measure, and partner rather than servant. The current state of global ecological unsustainability has made Naess state that he is optimistic about the twenty-second century but pessimistic about the twenty-first; humans have a long way to go.

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of being inherently fascist, antihumanist, antifeminist, and against having indigenous peoples share wilderness areas with nonhuman life-forms.³² As the articles in volume X will show, none of these criticisms are compatible with a sophisticated reading of Naess's writings on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has clear answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three

key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not, on first principles, embrace wide-identification? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that lead to long-term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable means? Third, how can deep ecology help resolve conflicts in environmental decision making when those conflicts result not from pseudorational thinking but from genuine value conflicts?

Throughout this essay, I have tried to show how Naess's life of rich and varied spontaneous experiences and internal tensions have shaped not only who he is as a person, but also who he is as a philosopher. Viewed separately, Naess's contributions to academic philosophy, social research, and ecological philosophy and activism can appear discordant, dilettantish, and incoherent. When, through careful study of his helical progression, his philosophical and personal maturation, the pattern of the whole unexpectedly reveals itself as a unity, the whole suddenly becomes much more than the simple sum of individual books and articles. With the distance of a meta-perspective, Naess's collective philosophical contributions can be seen as a mosaic—as a superordinate gestalt, in some sense, as a rich and inspiring, but inevitably fragmentary total view. Naess has breathed life back into the study of philosophy by turning its study back to life. With his cultivation of a meta-perspective, a whole, new (old) approach to philosophy and way of seeing the world emerges. This richly patterned mosaic, by encouraging us to celebrate our freedom and affirm life, can help us to reshape our relationship to each other and the Earth in new and promising ways.

Conclusion

It was only as a professor that I became aware of the difficulties of suppressing the significance of the development of feelings in human affairs while at the same time worshipping reason. Both are constantly needed.

Arne Naess, *Life's Philosophy*

The ten volumes of this series (along with a subsequent volume of conversations between Naess and myself on deep ecology and his philosophy)

SERIES EDITOR'S INTRODUCTION

make available for the first time access to the breadth and depth of Naess's philosophical thought. Efforts to judge the significance of Naess's philosophical oeuvre—assertions made in the first sentence of this essay—can now be taken up on an informed basis. When embarking on this process, it may prove beneficial to reflect on Henry Adams's insight on the fundamental limitations of communication, and especially the limits of communicating one's fragmentary total view, "No one means all he says, and yet very few say all they mean, for words are slippery and thought is viscous."³³ Spinoza ends the *Ethics* with the following remark: *Sed omnia praeclara tam difficilia, quam rara sunt* ("But all very clear things are as difficult as rare").

In *The Radical Spinoza*, Wienpahl translates the phrase more literally than usual, rendering *praeclara* as "very clear" rather than the typical "excellent."³⁴ The quest for clarity is painful and difficult as well as amaranthine. The alternative, however, is to abandon joy and freedom and thus meaning. This is the essence of Naess's distinction between being an *academic philosopher* and being a *philosopher of life*, between merely *functioning* and *living*. Drawing inspiration from Spinoza, Naess has cultivated a practice of both integrating reason and emotion *and* transforming negative emotions into positive ones. His challenge is before us and the frontier is long—the choice, however, is ours.

Editorial Approach

Naess has always written books as if they were exercises for himself, tentative formulations that chronicled his views at that very second but were always subject to change. As I indicated previously, many of the prior editions of his books were poorly edited and sparsely documented. Existing bibliographies were incomplete, and indexes (in the rare cases in which they existed) were always inadequate. Quotations were often transcribed incorrectly and ill-referenced. In addition, the breadth of his work was enormous and sometimes repetitive. Arriving at a plan for a representative *Selected Works* that would have a consistent format and design was no easy task.

All the selections for the *Selected Works* were made in close consultation with Naess. I would prepare recommendations from my master bibliography file and then, whenever we disagreed, we would discuss the pros and cons of the piece and whether it was appropriate for inclusion (this ap-

proach proved particularly helpful when we reached the *Selected Papers* volumes). We immediately made a decision to exclude works that were widely available and currently in print. Other important works, such as his dissertation, and his major work on lay people's conception of truth, his work on the semantics of democracy and ideological controversy, and his contributions to history of philosophy were more difficult to exclude, but the nature of the project as a selected works demanded such tough choices. I was encouraged by the fact that Naess often published articles that summarized or updated earlier works. In the end, I was able to reflect a significant portion of the ideas and concepts in these excluded works by including articles of that type in one of the three *Selected Papers* volumes.

The details of editing proved more complex. Much to my chagrin, I very humbly learned how much work goes into a project of this scale and complexity. We decided early on that the level of editing required to bring the prior publications up to the high standards of contemporary academic philosophical publishing would necessitate revised editions. We also decided that since we were preparing revised editions and Naess was alive and could review the work, we would make the role of the editor invisible and not include tedious footnotes chronicling all the changes, however significant they might be. The historical significance, intricacy, and sheer magnitude of *Interpretation and Preciseness* (SWAN I) warranted special consideration. For these reasons, we decided that it would be best to prepare only an edited version for this volume and not attempt a complete revision as with the other volumes. In the early stages of the project Naess and I worked together closely, intimately. In my effort to eliminate errors and to enhance readability, flow, and clarity of argument, I brought Naess question after tedious question when I first embarked on the project (particularly when I was in Norway as a Fulbright Scholar in 1996). After working through several manuscripts, Naess decided to place the remainder of the responsibility for revising and editing the manuscripts in my hands.

We have made our best effort to reconcile inconsistencies, make corrections, and chase down incomplete bibliographic references (in most cases no bibliographies existed for the original works). I regret, however, that some imperfections remain. I am also responsible for any new errors that have been introduced—their existence, unfortunately, is unavoidable. I am, however, heartened by a conversation I had with Naess midway through the project, after he had reviewed several drafts of revised manu-

SERIES EDITOR'S INTRODUCTION

scripts. He commented that at least 90 percent of my revisions resulted in improvement and that no significant misinterpretations had been introduced. Given the nature and complexity of this project, that sounded like odds I could live with.

Acknowledgments

A project of this magnitude, by its very nature, represents the labor and love of an entire community. It could never have gotten off the ground, much less been completed, without a fantastic and deeply committed team. I have been blessed by the opportunity to work with, learn from, and receive guidance and support from so many talented friends and colleagues. It's been a wild ride; I owe you all a tremendous debt of gratitude.

First, the inspiration for the *Selected Works* and the majority of its financial support are due to the foresight and generosity of "Miracle Doug," Douglas Tompkins, president of the Foundation for Deep Ecology (FDE). Thanks for your vision, Doug. Quincey Tompkins Imhoff, former executive director of the Foundation (and current vice president of the board), also deserves recognition for her tremendous support during the early years of the project, as do program directors Jerry Mander and John Davis. Special thanks also go to Sharon Donovan, the Foundation's publishing manager, who in the project's final years has guided it through a long and sometimes circuitous path to completion. The Foundation has also always had an amazingly gifted and dedicated staff. At one point or another, many of its staff had a hand in helping this project along—offering assistance at a key point, a kind word, inspiration, or simply good cheer and a smile. Thank you, Denise Wilson, Debi Barker, Esther Li, Lizzie Udwin, Julie Lindow, Miyo Sakashita, and Emily Lydgate.

I was also supported by the Fulbright Foundation with a senior research/teaching fellowship at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. Additional support came from Western Michigan University. Special thanks go to WMU's dean of the College of Arts and Sciences, Leonard Ginsberg, and to my chair, Thomas Bailey. My colleagues at Western Michigan University also deserve thanks for their tolerance and succor while I focused all my available energies on this project. I am grateful for their flexibility and generous support. Wil Emmert, one of WMU's Research and

SERIES EDITOR'S INTRODUCTION

Program officers, also deserves a great thanks for his patience and skillful assistance.

The project has been blessed with a distinguished advisory board—Robert S. Cohen, Bill Devall, Alan Drengson, Ingemund Gullvåg (deceased), Per Ingvar Haukeland, Kit-Fai Naess, Nicolas Rescher, George Sessions, Michael Soulé, Douglas Tompkins, and Jon Wetleson. All of the advisers offered significant assistance in one form or another. Bob Cohen graciously shared his expertise and offered invaluable advice, encouragement, and support throughout the project. Bill Devall gave encouragement and helped bring volume X to completion by coauthoring its preface. George Sessions offered advice on the selections for volume X, provided guidance, and carefully reviewed a draft of this introduction. His suggestions greatly improved its flow and clarity. Kit-Fai Naess's tremendous moral support and great assistance in locating obscure documents and preparing bibliographies were invaluable.

Alan Drengson's contribution as a project adviser and in the project's final year as Associate Editor deserves special mention. At a crucial time, when the project was stalled in its later stages, Alan stepped up to the plate and played a key role in helping shepherd the project to completion. In particular, he took over most of the day-to-day project-coordination responsibilities for the final year of the project. He reviewed the copyedited manuscripts for volumes I, VIII, IX, and X, oversaw preparation of the author's prefaces to each volume and the editors' prefaces to volumes VIII, IX, and X, and reviewed the final manuscript proofs. This was not an easy task. I owe Alan a great debt for his fortitude, commitment, and generosity. For his contribution to the difficult and taxing responsibility of overseeing the final preparation of volume I, he has been credited as its sole editor.

I am lucky to have been supported by two astonishingly capable, committed, and patient project assistants. Kim Zetter played a critical role in getting the project off the ground and keeping it on schedule for the first three years. Later, Barbara Pijan helped steer the project back on track and over some awkward obstacles after it had run off course. Their talent and dedication played a major role in bringing to life the books before you. Thank you, Kim and Barbara, for your stalwart devotion to the project.

The beautiful and elegant design of the series is the work of Tomatsu Yagi and his nephew Akira Yagi. Ralph Fowler played a significant role in executing the Yagis' design and by filling in any missing gaps. Ralph also

SERIES EDITOR'S INTRODUCTION

performed the typesetting for volumes II–VII. The skillful and efficient crew at BookMatters performed the remainder of the typesetting. Katherine Silver handled the Brobdingnagian task of project management on volumes I and VIII–X and the last crucial stages of the project with aplomb, attention to detail, and fortitude.

The bulk of the project's copyediting was performed by the meticulous and supertalented Anne C. Collins, Ph.D., copyeditor extraordinaire. Additional copyediting was provided by Mary Anne Stewart and Kathy Walker. Indexing was performed by the immensely competent Nancy Mulvaney of Bayside Indexing Service, Julie Shawvan, and Leonard S. Rosenbaum. Proofreading was provided by Carrie Pickett.

Ingemund Gullvåg translated *Which World Is the Real One?* Iver Ørstavik provided the translation of "Experts' views on the inherent value of nature." The original editions of Naess's texts were keyed or scanned by the able and efficient crew at AgAccess—David Katz, Karen van Eppen, Jacob Katz, Rachna Boon, and Tim Rice. Additional keying of articles for the *Selected Papers* volumes was provided by Nancy Ropecka and Jane Drengson. Barbara Pijan, d Jones, Tony Hainault, and Debbie Reid deserve thanks for their careful and thorough transcribing of more than thirty-five hours of discussions with Arne Naess. Thanks are also owed to Tim Quick for his help with bibliographic research for volumes I and VIII–X, and to Kelly McKernan for assisting Alan with photocopying and faxing. In addition, a special thanks goes to Robert P. Goldman, Sarah Kailath Professor of Sanskrit and Indian Studies at the University of California Berkeley, for generously and graciously offering assistance on contemporary Sanskrit and Hindi terms.

I am grateful to the dedicated and very patient staff at Kluwer Academic Publishing. I am sad that our original editor, the immensely talented Annie Kuipers, who first recognized the importance of this project, did not live to see it come to print. Stephanie Harmon, Annie's replacement, worked closely with me on editorial matters and on finding high-quality recycled paper, cloth, foil, and other materials that meet the strict environmental considerations of FDE. In the final five years, the able and gifted Charles Erkelens was our editor.

Additional advice and moral support were provided by colleagues, friends, and family: Aimee Carroll, Kirsten Coyne, Paul Craig, Neal Goodwin, Byron Hahn, Ladislav Hanka, Alastair Hannay, Anna Leidberg-

SERIES EDITOR'S INTRODUCTION

Miron, Danny Moses, Richard Norgaard, Max Oelschlaeger, Brian Recht, Stephanie Sarvar, Ed Saxon, Geir Michael Sommerhein, Petter Sorum, and Kristin Walstad. Thanks for your efforts to coax me out of the cave.

Special thanks go to d and Reuben for their forbearance and succor. Someday, all too soon, Reuben will recognize that the invisible “work fairies” that were constantly pulling me back to my office don’t actually exist. I can’t wait.

Most of all, thanks to Arne Naess for placing his trust in me—it’s been a gift, something like an extended trudge up to Tvergastein, but without the fresh air and perspective. Taking on this project has been somewhat like receiving Pandora’s box as a present—all sorts of ills and plagues reared their heads along the way. I often felt that I was on a never-ending climbing descent in the night. I was always wondering about rappelling off my rope into the abyss.

The SWAN has taken flight, and I have landed on firm ground—I think? In all seriousness, I learned invaluable lessons. The more I worked through Arne’s writings, the more open-minded and optimistic I became. I found myself cultivating perspective and looking at the problems and challenges before me with fresh insights. I also found myself responding with more grace and equanimity in my efforts to counteract the numbing effects of contemporary society.

It is strange and ironic, however, that in being the series editor for the *Selected Works* of the father of deep ecology I spent so much time inside, chained to a desk. But this is part of the paradox of working with Arne Naess. I am reminded of one of my favorite poems—Gary Snyder’s “Axe Handles.” The last few lines read:

Pound was an Axe,
Chen was an axe, I am an axe,
And my son a handle, soon
To be shaping again, model
And tool, craft of culture,
How we go on.

And then it makes sense.

Harold Glasser
2004

Notes

1. In writing this essay, I found myself drawing on more than twelve years of friendship with Arne Naess. A simple bibliography could not do justice to describing how this subtle and multilayered gestalt has been formed. My perception of Naess and his work has been shaped by more than thirty-five hours of transcribed conversations between us, countless other conversations, letters, scraps of paper, e-mails, and Arne's copious annotations in my own books and articles. Camping trips, bouldering, hikes, and cross-country skis have also helped inform my understanding of Arne Naess the fiercely competitive, playful, elfin trickster, who springs to life in nature. I have benefited from three extended visits to Norway, including a Senior Fulbright at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. I have also spent other stimulating periods of time with Arne in Svalbaard, England, California, and the deserts of Arizona and Nevada. Finally, and probably most important, I have been inspired and forever changed by my own reading and editing of his work. In this regard, both previously published and unpublished materials have been influential in forming my own perspective on Arne Naess the philosopher. One key published source has been Naess's "How my philosophy seemed to develop," in *Philosophers on Their Own Work*, edited by Andre Mercier and Maja Svilar (Bern: Peter Lang, 1983), pp. 209–26 (in SWAN IX). Another source for insightful material on Naess and A. J. Ayer (as well as six of their contemporaries) is a book created from debates by philosophers for Dutch National Television. See, especially, "The glass is on the table: An empiricist versus a total view," in *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), pp. 11–68 (in SWAN VIII). Finally, additional perspective was offered by an article that discusses Norwegian philosophy from the end of the Second World War to just before 1980: Arne Naess and Jon Hellesnes, "Norway," in *Handbook of World Philosophy Since 1945*, edited by John Burr (Westport, CT: Greenwood Press, 1980), pp. 159–71.

On some of the fine points of this essay, I have benefited from extended conversations with my colleague and old friend George Sessions. I have also profited, over the years, from the significant literature that has been created to shed light on Arne's life and work. Many of the ideas and thoughts introduced in this essay—drawn from my own firsthand experiences with Arne—can also be found in these sources. In many cases, issues only touched on here are taken up in much more detail in those sources. Five key references for historical material on Naess and the evolution of his philosophical approach are identified below (two of which are videos). A wealth of additional material is available in the five festschrifts for Naess (see details in note 15 below). The

SERIES EDITOR'S INTRODUCTION

first of the festschrifts, *In Sceptical Wonder: Inquiries into the Philosophy of Arne Naess on the Occasion of His Seventieth Birthday*, edited by Ingemund Gullvåg and Jon Wetlesen (Oslo: Universitetsforlaget, 1982), contains the most thoroughgoing analyses and critiques of Naess's earlier philosophy that I am aware of, and many of the articles have insightful responses by Naess.

Books

Warwick Fox, *Toward a Transpersonal Ecology: Developing New Foundations for Environmentalism* (Boston and London: Shambhala, 1990). See, especially, chapter 4, "Arne Naess and the Meanings of Deep Ecology."

Ola A. Hegdal and Tore Strand Olsen (illustrator), *Jeg, Arne Naess: Et Tegnet Liv* (Arne Naess: A cartoon story of my life) (Oslo: Kagge Forlag, 2001). A unique and insightful look at Arne's life, based on an idea from Arne's wife, Kit-Fai.

David Rothenberg, *Is It Painful to Think? Conversations with Arne Naess* (Minneapolis: University of Minnesota Press, 1993).

Crossing the Stones: Arne Naess (Oslo: Norwegian Broadcasting Corporation, 1991), 47 minutes.

The Call of the Mountain: Arne Naess and the Deep Ecology Movement (Amsterdam: ReRun Produkties, Postbus 93021, 1090 BA, 1997), 50 minutes.

2. On Naess's effort to expand the concept of reason to incorporate emotions and feelings, see Arne Naess with Per Ingvar Haukeland, *Life's Philosophy: Reason and Feeling in a Deeper World*, translated by Roland Huntford, foreword by Bill McKibben, introduction by Harold Glasser (Athens and London: University of Georgia Press, 2002). As a testament to Naess's interest and influence in Norway, I note that in a country of about 4.5 million people, 150,000 copies of the Norwegian edition of *Life's Philosophy* have been sold. For a fine example of Naess's use of mythopoetics, see Arne Naess and Johann Brun (photographer), *Det Gode Lange Livs Far: Hallingskarvet sett fra Tvergastein* (The good, long life's father: Hallingskarvet from Tvergastein) (Oslo: N. W. Damm and Son, 1995). For other examples, see Naess's article on Tvergastein, his "Letter to the King of Nepal," and some of his writings on deep ecology in volume X of the *Selected Works*.
3. Most of these questions were drawn from Naess's discussion with Sir Alfred Ayer on the nature of philosophy and the problems it seeks to address (Naess and Ayer, "The glass is on the table," p. 14).
4. See Naess's "Ecosophy and gestalt ontology" in SWAN X.
5. Jakob von Uexküll, "A stroll through the world of animals and men: A picture book of invisible worlds," in *Instinctive Behavior*, edited by Claire H. Schiller (New York: International Universities Press, 1957), p. 14.

12. From about 1845 to 1910, Hegelianism dominated Norwegian philosophy. This period is often referred to as the "dead period" of Norwegian philosophy, not because of Hegelianism but because it was characterized by a dearth in publishing.
13. Personal communication, April 30, 1997.
14. Alastair Hannay, "Norwegian philosophy," in *The Oxford Companion to Philosophy*, edited by Ted Honderich (Oxford: Oxford University Press, 1995), pp. 626–27.
15. Gullvåg and Wetlesen, *In Sceptical Wonder*; Alan Drengson, ed., *The Long-Range Deep Ecology Movement and Arne Naess*, special edition of *The Trumpeter* 9 (Spring 1992); Rana P. B. Singh, ed., *Environmental Ethics and the Power of Place: Festschrift to Arne Naess* (Varanasi, India: National Geographical Journal of India, 1994); Nina Witoszek and Andrew Brennan, eds., *Philosophical Dialogues: Arne Naess and the Progress of Ecophilosophy* (Oslo: Centre for Development and the Environment, 1997; Lanham, MD: Roman and Littlefield, 1998); Andrew Light and David Rothenberg, eds., *Arne Naess's Environmental Thought*, special edition of *Inquiry* 39 (June 1996).
16. Arne Naess, *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre*, translated by Alastair Hannay (Chicago: University of Chicago Press, 1968). In the 1970s, philosophy was still influenced by the events of the Second World War. Heidegger's flirtation with National Socialism and the Hitler regime, and his unusual way of expressing himself, made it difficult for him to be considered a great philosopher. Naess's book on four contemporary

SERIES EDITOR'S INTRODUCTION

philosophers was seen as unique because he interpreted in a scholarly and positive way both Heidegger and the fiercely anti-Heideggerian philosopher Rudolph Carnap, a logical empiricist. Carnap, who was forced to flee Nazi Germany, could not fathom how Naess, as an old friend, could present positive discussions of Heidegger and himself in the same book. The other two philosophers included in the book, Wittgenstein and Sartre, also held completely incompatible views of philosophy, but Naess accorded them equally high positive appreciation.

17. For example, works by Naess that are still in print, such as *Ecology, Community, and Lifestyle: Outline of an Ecosophy*, translated and edited by David Rothenberg (Cambridge: The University Press, 1989), and *Life's Philosophy* (2002; see note 2), were not included, for obvious reasons.
18. In "How my philosophy seemed to develop," p. 215, Naess mentions the particularly strong impression, the magnificent expansion of his own "life's frame of reference," made by H. G. Wells's early popularization of the history of life, *Outline of History* (New York: Macmillan, 1920).
19. For detailed discussions of Naess's assessment of logical empiricism, see Arne Naess, "How can the empirical movement be promoted today? A discussion of the empiricism of Otto Neurath and Rudolph Carnap," in *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. Vandormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), pp. 107–55 (in SWAN VIII). (The original German version of Naess's article, "Wie Fördert Man Heute die Empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolph Carnap," was written during 1937–39.) For Naess's experiences attending the Schlick seminar, see Arne Naess, "Logical empiricism and the uniqueness of the Schlick seminar: A personal experience with consequences," in *Scientific Philosophy*, edited by Friedrich Stadler (Dordrecht: Kluwer Academic, 1993), pp. 11–25 (in SWAN VIII).
20. Naess, "How my philosophy seemed to develop," p. 222.
21. See Arne Naess, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior or, more colloquially, Science as behavior), Inaugural Dissertation (Oslo: Norwegian Academy of Sciences, 1936).

Schilpp (Chicago: Northwestern University Press, 1939), p. 597, as quoted in Wallace I. Matson, *A New History of Philosophy*, vol. 2 (San Diego: Harcourt Brace Jovanovich, 1987), p. 454.
23. Naess, "How my philosophy seemed to develop," p. 223. For more details, see Richard McKeon and Stein Rokkan, eds., *Democracy in a World of Tensions* (Chicago: University of Chicago Press, 1951). Naess, as the scientific leader of the project, was viewed as a UNESCO administrator; he was only credited as

SERIES EDITOR'S INTRODUCTION

- being the author of the questionnaire itself and the summary paper, although he was intimately involved with the project at all levels.
24. Naess went on to perform a reconnaissance of Tirich Mir (25,263 feet) in the Hindu Kush in the summer of 1949. He then led the successful Norwegian first-ascent team in 1950. The expedition, which included botanical and geological assessments of the region, is chronicled by the team members in Naess et al., *Tirich Mir: The Norwegian Himalaya Expedition*, translated by Sölvi and Richard Bateson (London: Hodder and Stoughton, 1952). Naess successfully pursued a second, vastly more technical expedition to Tirich Mir in 1964. His "The south wall of Tirich Mir East," *Himalayan Journal* 26 (1965): 97–106, discusses this expedition and includes interesting commentary on expedition philosophy and climbing ethics. The article appears in SWAN X, along with other papers on Naess's relationship to mountains and views on mountaineering.
 25. Arne Naess, "Reconnaissance, 1949," in *Tirich Mir*, p. 22.
 26.  29. For a discussion of nonanthropocentrism as part of an ongoing historical tradition with ancient roots, see George Sessions, "Ecocentrism and the anthropocentric detour," in *Deep Ecology for the Twenty-First Century*, edited by George Sessions (Boston: Shambhala, 1995), pp. 156–83. For details on Douglas's effort to save the Everglades, see Marjory Stoneman Douglas, *The Everglades: River of Grass*, rev. ed. (Sarasota, FL: Pineapple Press, 1987).
 30. See Arne Naess, "The shallow and the deep, long-range ecology movement: A summary," *Inquiry* 16 (1973): 95–100 (in SWAN X). For a more detailed, mature version of deep ecology, see Naess, "The deep ecology movement: Some philosophical aspects," *Philosophical Inquiry* 8 (1986): 10–31 (in SWAN X). For a concise overview of deep ecology that chronicles its key evolutionary changes and identifies the distinctions among the "deep ecol-

SERIES EDITOR'S INTRODUCTION

ogy approach to ecophilosophy," the "deep ecology movement," and Naess's "Ecosophy T" (a particular deep ecological total view), see Harold Glasser, "Deep ecology," in *International Encyclopedia of Social and Behavioral Sciences*, edited by Neil J. Smelser and Paul B. Bates (Oxford: Pergamon, 2001), pp. 4041–45. For a detailed discussion of deep ecology as an ecophilosophical approach with special attention to its policy implications and a discussion of deep ecology's relationship to Naess's earlier philosophical work, see Harold Glasser, "Naess's deep ecology approach and environmental policy," *Inquiry* 39 (1996): 157–87 (reprinted in Witoszek and Brennan's *Philosophical Dialogues*).

31. For anthologies on the deep ecology movement, which include articles by Naess and other deep ecology supporters, see George Sessions, ed., *Deep Ecology for the Twenty-First Century* (Boston: Shambhala, 1995), and Alan Drengson and Yuichi Inoue, eds., *The Deep Ecology Movement: An Introductory Anthology* (Berkeley, CA: North Atlantic Books, 1995).
32. Naess rarely responds directly and definitively to these criticisms—this is not his nature. Siri Naess, however, made an interesting effort to explore the potential of using Naess's Ecosophy T as an inspiration for a feminist normative system in her "Self-realization," in *In Sceptical Wonder*, pp. 270–81. She concluded that while Ecosophy T and her System F have much in common, Ecosophy T goes further by extending to all living beings its concern for activeness and creativity in relation to problems, egalitarianism, and support of the suppressed and exploited.

Author's Introduction to the Series

At ninety-two it is a great honor to be still alive and to witness the publication of my selected works in English. Few philosophers have their work published in a series, fewer still receive this honor before they die. When I was originally approached with the idea of publishing my complete works, I was overwhelmed and overjoyed, but added that not all my books and articles were important enough to merit such an honor. Selected works? Yes, and I am extremely grateful for this initiative and the final result, which presents a representative selection of my work from the earliest to the most recent. [*The Selected Works of Arne Naess* are hereafter referred to as SWAN.]

My interest in philosophy began with Spinoza's *Ethics*, which as a seventeen-year-old I was fortunate to read in Latin. I appreciated Spinoza's grand vision and trusted him implicitly as a person. I accepted that human beings could, and should, have a general outlook with the grandeur of Spinoza's, but I recognized that our individual views on this grand scale will not be identical. Through the years I have realized that there is a splendid variety of interpretations of Spinoza (SWAN VI and IX). His texts are exceptionally rich. As the years have gone on, I have focused on how he leads us to realize we can increase our freedom and sense of connection with the world through strengthening and intensifying our *positive* emotions. For example, loving and caring for our place and others leads to an expansive sense of being part of a much larger world. Emphasizing hatred and anger, on the other hand, makes us feel smaller and isolated from the world. Spinoza, as I interpret him, would express this by saying that "We are as large as our love." Increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow.

Before I left gymnasium [the end of secondary education] the headmaster asked me, "What do you intend to be?" My immediate answer was "A philosopher." In fact, I had already conceived of myself as one. I viewed the

AUTHOR'S INTRODUCTION TO THE SERIES

writings of many contemporary philosophers that I was familiar with, however, as vague and airy and certainly not as inspiring as Spinoza.

My doctoral thesis in philosophy of science was an effort to remind us that in science the content of a theory is not independent of research behavior—the activities of observing, confirming, disconfirming, and so on, and that these are set within a deep context of place, history, and culture. Later, as a postdoctoral researcher at the University of California at Berkeley, I studied the behavior of experimental psychologists doing animal research.

In 1934 and 1935 I studied in Vienna and while there became a member of the famous Schlick seminar, the main discussion group of the Vienna Circle. Their quest for clarity and cordial cooperation in pursuit of knowledge led me to appreciate that “What do I mean?” is an open question. I concluded that we never intend to express anything extremely definite, even in mathematics or symbolic logic. I saw the importance of using empirical methods to find out how we actually use certain expressions and sentences. I developed and applied a wide variety of such methods, which became part of the core for the empirical semantics that runs through my work. I continued to do this type of research into the 1990s, my last project being one in which I questioned experts and policy makers about their ideas of values intrinsic to the natural world (in SWAN X).

In one of my earlier studies, I reviewed about 700 articles from philosophers concerning their use of the word *truth*. For the most part, I found these unconvincing and soon started on empirical studies of the use of *truth* among ordinary nonprofessional people and schoolchildren (in SWAN VIII). Many philosophers seemed to assume that ordinary people hold very naive views about these deep matters. I found through research that, on the contrary, the views articulated by these “ordinary” people were every bit as sophisticated as those held by professional philosophers. This reinforced my conviction that, generally, we greatly underestimate ourselves. Much academic philosophy was narrowly focused and abstract. Philosophers who elicited interest in wide-ranging issues of practical and global importance, such as nonviolence and social justice, have in my lifetime said things that were considered creative, but often too far out. In spite of consistent proclamations that science neither would nor could take over all the problems discussed by philosophers, I tried to argue in ways that reminded readers of science done as open inquiry, and I tried to emphasize that it is occasionally

AUTHOR'S INTRODUCTION TO THE SERIES

necessary to perform empirical research to illuminate or support a philosophical viewpoint.

My empirical and historical research led me to realize that there are no certainties and that there is a great diversity in our spontaneous experience as well as endless ways to describe and appreciate the complexities and values of the world. Thus, I realized that I am one of those lifetime seekers that the ancient Greeks called a *zetetic* (see SWAN II and VIII). From my research on scepticism and the foundations of science and logic, it became clear to me that pluralism (every event has many descriptions and possible outcomes), possibilism (anything can happen), and a healthy scepticism (always seeking the truth but never claiming it) make up the most consistent approach to respecting the perspectives and experiences of others, human and nonhuman.

From my empirical studies of semantics, and from my knowledge of several languages, I came to appreciate the complexity of communication. Being committed to Gandhian nonviolent communication, I saw the importance of avoiding dogmatism and fanaticism. One of the most important discoveries coming from this research, leading to the publication of my major book, *Interpretation and Preciseness* (SWAN I), was the insight that we cannot avoid values in any field of endeavor or research. There are no value-free inquiries or theories. Even if we refuse to express our values, this is itself an expression and choice of values. We must, therefore, be clear about our value choices and try to make them explicit. The choices we make, as Spinoza pointed out, shape the quality of our lives, and values emphasizing positive emotions or feelings are expansive and lead to our growth. We must become ever more aware of our choices and the values involved. Even pure logic assumes certain norms. Empirical research can shed light on these matters. My colleagues in philosophy often found my empirical work perplexing. I, in turn, grew to underrate the necessity of visiting great centers of philosophy, as I preferred to be close to or in the mountains.

When I visited the United States, it was mostly to climb in the mountains or walk and camp in the desert. On one fortunate visit, I dropped in at the graduate students' discussion room at Harvard. Speaking with students who were writing their doctoral theses in philosophy, I understood that my knowledge of contemporary philosophy, and of recent important contributions in its various fields, was narrowly limited to special themes of lively personal interest. Even in later years, the tendency to take personal inclina-

AUTHOR'S INTRODUCTION TO THE SERIES

tion very seriously colored my contribution to the philosophical literature. As can be seen, though, from the titles in these *Selected Works*, my strongly felt interests span a rich variety of fields, philosophical traditions, and movements.

Since childhood I have experienced an intense joy in being together with animals and plants and in contemplating the immense evolutionary development of life on earth over millions of years. From an early age I also developed an intense love for mountains and for being in them. Much of my creative philosophical work was done at Tvergastein, my mountain hut in Norway (see SWAN X). My devotion to outdoor life is in the Norwegian tradition called *friluftsliv* (literally, free-air-life). In many respects, I approached philosophical and cross-cultural studies as if I were a field ecologist or naturalist. It was against this background that my work from the 1960s onward focused with close attention on cultural diversity, biodiversity, sustainability, and the deep ecology movement.

My work since the Second World War has been increasingly within movements such as those furthering social justice, peace, and ecological responsibility. During the war, I engaged in anti-Nazi activism, and from that time also in promilitant Gandhianism, a nonviolence that is not pacifist in the usual sense but insists that if it is a bloody fight for justice against injustice, we seek "the center of the conflict" and, if necessary, cooperate with people who use arms. During the Cold War, I participated in the "third side," against both communism and extreme anticommunism, for example, as the scientific leader of a UNESCO project bringing Marxist and anti-Marxist politicians and political science researchers together in an unbiased discussion of the essence of democracy and freedom. Some of the relevant publications are included in SWAN IX.

The broad spectrum of books and articles included in the *Selected Works* represents, in many ways, a chronicle of my passions and influences. The *Selected Works* record, albeit in an inevitably fragmentary way, one possible expression of these. My dream and hope is that some readers will be inspired by their sheer variety, and that young philosophers will be encouraged to let strong personal motivations steer their studies.

Working habits vary. Some people write an article and go on to the next without looking back on the old one; others come back from time to time, radically revising and changing the old one. The latter is my way of working. Lecturing in many places about these subjects, I have found it

AUTHOR'S INTRODUCTION TO THE SERIES

natural to revise the old manuscripts until sometimes very little is left of the original. Therefore, I have always viewed my writing as preliminary; a year, five years, ten years after publication of the first editions I have itched to revise, *thoroughly* revise them. When my first book was printed in 1936, I went to watch the hulking presses printing out one page at a time. I was terrified, thinking of mistakes or some awkward sentences being duplicated again and again.

When I was offered the opportunity to have a selected-works series published, I immediately thought I would like to review all my work and ask how, from today's perspective, I might answer the difficult questions I had earlier attempted to probe. Such a task would have been a particularly difficult proposition, because although many of my books and articles contain new ideas, the ideas are often not developed as well as I might have hoped. But alas, I am saved—at my age there is not time for me to accomplish such a comprehensive reevaluation of my work; I do not even have the capacity to do it now in any case.

Who could contemplate undertaking a publishing project of such ambitious proportions? Douglas Tompkins, mountaineer, entrepreneur, protector of wilderness in Chile and Argentina, and creator of the Foundation for Deep Ecology, is such a person. "Miracle Doug," as I call him, likes the idea that the deep ecology slogans and the deep ecology approach were introduced by a philosopher. I am grateful to him for his firm conviction, inspiration, and great generosity. My gratitude, however, extends well beyond my thanks to Doug, to others who have supported and championed this project.

Quincey Imhoff, when executive director of the Foundation for Deep Ecology, supported SWAN with generous grants and other contributions. SWAN has also benefited from faithful assistance and cooperation in the preparation and editing of the manuscripts. The late Professor Ingemund Gullvåg prepared the initial translation of *Which World Is the Real One?* (SWAN III). Professor Alastair Hannay translated the first edition of *Communication and Argument* (SWAN VII) and offered invaluable suggestions for improving the readability of the first editions of *Scepticism* (SWAN II), *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), and *Gandhi and Group Conflict* (SWAN V).

Most of all, however, I am grateful to Harold Glasser, the series editor, and his assistant, Kim Zetter, who oversaw all aspects of the project from design to production. Glasser's unique combination of intellectual tenacity,

AUTHOR'S INTRODUCTION TO THE SERIES

attention to detail, mastery of my work, and cooperative spirit made him a natural to take on the monumental task of selecting and editing my works. Glasser not only labored to improve the English and clarity of each manuscript, but his keen ability to ferret out countless technical and pedagogical errors has resulted in substantial new editions of volumes II–VII that are both far more comprehensible and accessible than the originals. I thank him for his valiant work on this project, both during his stay in Norway as a visiting Fulbright professor, where we collaborated on a strategy for revising the previously existing material, and in the subsequent years it has taken to complete the project.

From the beginning of the SWAN Project in 1994, Alan Drengson has encouraged and helped to move this work forward in numerous ways. Especially in the last crucial stages of completing volumes I, VIII, IX, and X, his help and editorial oversight have been invaluable. Thanks for his devotion, good humor, and positive enthusiasm. Thanks to both Drengson and Tim Quick for their extensive bibliographic research. Thanks to Bill Devall for his support and encouragement and especially his help on the completion of volume X, *Deep Ecology of Wisdom*. Thanks to Anne Collins for her outstanding work as the copyeditor of the SWAN volumes. Thanks to George Sessions for his support and encouragement.

Last, but certainly not least, immeasurable thanks go to my wife, Kit-Fai Naess, who has worked beside me throughout the years to provide invaluable assistance, encouragement, and inspiration.

Author's Preface to This Edition

SWAN V is my third book on Gandhi, and, as stated in the subtitle, it explores *satyāgraha* and its “theoretical background.” A volume on the practice of *satyāgraha*, the way of militant nonviolence, was to follow. It was to be written by my old collaborator on nonviolent action, Johan Galtung. However, my friend Johan had other, more pressing themes to write about, such as the Cultural Revolution in China. There was no such volume on nonviolence.

A central theme in Gandhi's philosophy is central to this book. It is perhaps most simply stated in these passages from Gandhi, where he expresses his feelings for the oneness and divine nature of all beings.

I know that you had naturally the art of looking upon trees and animals as friends. I wanted you to extend the idea so as not to feel the want of friends from outside. [There] should be a definite realization that personal friends and relations are no greater friends than strangers of the human family and bird, beast and plant. They are all one, and they are all an expression of God if we would but realize the fact. . . .

(*The Collected Works of Mahatma Gandhi*, vol. 51, p. 57)

There is nothing inanimate for Him. We are of the earth and earthy. . . . I feel nearer God by feeling Him through the earth. . . . [I] rejoice in establishing kinship with not only the lowliest of human beings, but also with the lowest forms of creation whose fate—reduction to dust—I have to share. . . .

(*Ibid.*, vol. 45, p. 80)

Thus, we are most intimately connected with every living creature in the world and with everything that exists; everything depends for its existence on everything else. . . . [Every] obstacle which we place between ourselves and the sky harms us physically, mentally and spiritually.

(*Ibid.*, vol. 49, p. 295; the above three passages are quoted in Power 1991: 100–102)

AUTHOR'S PREFACE TO THIS EDITION

There is another central theme in Gandhi's philosophy that needs mentioning: "Fearlessness is indispensable for the growth of the other noble qualities. How can one seek Truth, or cherish Love, without fearlessness?" (Power 1991: 109). "I believe that, where there is only a choice between cowardice and violence, I would advise violence" (ibid., p. 110). I try in a special chapter to interpret in this way the violence expressed in the 1970s by militant blacks against whites. As Gandhi might have said, Yes, there has been timidity among blacks facing arrogant and violent whites. In such cases, violence against whites may sometimes be the only way to overcome fear. Gandhi recognized that sometimes we have to act with determination and force to overcome fear and past anger so that we can move on to a nonviolent way of relating and acting.

The term *self-realization* as used at my Level 1 verbalization of a deep ecology total view is closely related to the term as used by Gandhi. In his doctoral thesis, *Gandhi and Deep Ecology: Experiencing the Non-human Environment*, done at the University of Salford, Shahed Ahmed Power documents in detail the remarkable relations between Gandhian and deep ecology thinking.¹ Only in the last years of his long life did Gandhi seem to admit with regret that sometimes human beings may be forced to kill or even exterminate "dangerous" animals.

Note

1. So far (2004) this thesis is unpublished, and if published it might be shortened and the relation to deep ecology neglected. The original dissertation can be obtained by writing to Dr. Shahed Ahmed Power at Environmental Resources Unit, University of Salford, Salford, England M5 4WT.

Author's Foreword to the First Edition

Since the 1950s and 1960s, Gandhi's teaching has acquired a new and unexpected significance. Technical and industrial development has put most decisions that touch the individual and his local environment into the hands of specialists. In addition, the division, or rather fragmentation, of labor has proceeded unhampered and has contributed to the unsurveyable character of these developments. Partly as a consequence, the traditional parliamentary procedures in Western democracies have degenerated to the extent that they neither furnish decisions that express "the will of the majority" (no such thing exists in the area of specialist knowledge) nor take sufficient care of vital minority interests. Reconsideration of philosophies of direct action has forced itself on the impatient and underprivileged.

Racial and cultural minorities have made use of violent means or, rather, have lowered restraints against the outbreak of violence. This anti-Gandhian development has, however, underlined the importance of Gandhi's teaching of self-respect — and the feeling of "being something" — as a necessary condition of nonviolence. Outbreaks of violence in ghettos and universities have been followed by despair: "the establishment" has at its command a superior capability to perpetrate violence. Chaos helps the more sinister forces on both sides to increase their power.

In the West, majorities still indulge in the righteous repression of minorities, forgetting that the traditional democratic procedures that were designed to protect minorities can work only imperfectly in technocracies. Gandhi himself reacted against majority rule and the utilitarian precept, "the greatest happiness for the greatest *number*." In his fight for minorities, his motto was "the greatest good for *everyone*," and the kind of fight he led based on direct, nonviolent action, is widely applicable to the problems of the underprivileged.

AUTHOR'S FOREWORD TO THE FIRST EDITION

The evils of great cities and suburban unlife have made Gandhi's fanatical antimetropolis attitude and his ideals of decentralization (the *panchayat* system) discussible. His tendency to support agriculture and decentralized industry in villages and small towns in order to stop the disastrous flight of peasants to the great cities is quite modern. Gandhi's utopia is one of the few that shows ecological balance, and today his rejection of the Western world's material abundance and waste is accepted by progressives of the ecology movement. A decade ago, Gandhi tended to be denounced as a reactionary dreamer by both Marxist and anti-Marxist economists. Now they are forced to take his conclusions seriously.

Gandhi did not want followers, and we cannot today submit to his leadership. However, we can, and I think must, consider his life and teaching when groping for solutions to our problems.

This book tries to concentrate on central topics of Gandhi's teaching. The religious and philosophical background has been given more space than usual. Our questions are: What has a completely secularized technocracy to offer? How can we replace the vast religious or philosophical sources of energy that have been available in all great societies? In searching for answers, it is important to find out to what extent the religious thought of Gandhi was independent of dogma and myths that today have no chance of being accepted as truths. In this respect, it is not only a question of where Gandhi stands in matters of dogma and myths, but of where the whole world of modern Buddhist and Hindu thinking stands. As will be made clear in what follows, the Gandhian approach is surprisingly free from dogma, and it is even able to accommodate the militant atheist among "believers in God." (He or she must be *militant*, however!)

The studies resulting in the conclusions of this book have been generously supported by the Norwegian Research Council for Science and the Humanities, and have also benefited greatly from a trip to Varanasi, which allowed me to become familiar with contemporary Gandhian groups in the motherland. The small but resourceful group of mostly young people who have tried to apply Gandhi's principles have been a constant source of joy and consolation to me when struggling with the vast theoretical questions of nonviolence. To them I owe a special debt of gratitude.

This book, which was originally planned to be the first volume of a more comprehensive work, will have a sequel by Professor Johan Galtung

AUTHOR'S FOREWORD TO THE FIRST EDITION

dealing with the practical implementation of Gandhian norms in contemporary societies. Professor Galtung also cooperated with me in the writing of this book. I hope that his now independent work will soon be available because a theoretical background is worth little without a practical foreground.

I would like to thank Alastair Hannay for his generous efforts to improve my English. I am also grateful to the publishers of my book *Gandhi and the Nuclear Age* (1965) for permission to use material from that work. Chapter 1 is taken, with slight alterations and additions, from pages 3–15 and 21–23 of that work; chapter 5 contains material from pages 81–92 and 98–106.

I

Gandhi's Experiments

Gandhi: Merely a Man

We find two diametrically opposed views of Mohandas K. Gandhi's moral stature. One has it that, ethically speaking, he was nearly perfect. Albert Einstein said of him, for instance, that generations to come would scarcely believe that such a man actually walked this earth, and in a collection of essays that appeared under the title *Gandhi Memorial Peace Number* (Roy 1949), a large number of eminent persons accord Gandhi the highest of praise as a moral being. We must also ask ourselves, however, what exactly is the nature of Gandhi's contribution and what is the basis for the tremendous esteem and adulation in which he has been held. For with regard to his own moral achievement, we find a second opinion that is, perhaps, as near the truth as the first: the opinion that Gandhi was often mistaken and that it would be wrong to take him unreservedly as a moral example for everyone.

The best known representative of this latter and more modest view happens to be Gandhi himself. "I claim no infallibility. I am conscious of having made Himalayan blunders . . ." (quoted in Pyarelal 1932: 133; also in Prabhu and Rao 1967: 9). There are other people also who firmly accept that he fell short of his own very high aims. The best collection of Gandhi's teaching, *The Mind of Mahatma Gandhi*, compiled by Ramachandra K. Prabhu and U. R. Rao (1946, revised and enlarged in 1967), opens with two chapters in which Gandhi speaks of his own personal imperfection, his mistakes, their painful consequences, and his unrequited desire for support.

Like many other strong personalities, Gandhi was authoritarian in his family life and, perhaps without clearly perceiving it himself, pressed his wife and eldest son into conformity with his own ideas. Gandhi admitted this and elaborated the point by saying that it was especially in his early life, with its violent changes of lifestyle, that he was not aware of his own

GANDHI'S EXPERIMENTS

coercive powers and that he hoped his younger sons did not have as bad a time as his eldest. About his first son, Gandhi says:

His grievance against me has always been that I sacrificed him and his brothers at the altar of what I wrongly believed to be public good. My other sons have laid more or less the same blame at my door, but with a good deal of hesitation, and they have generously forgiven me. My eldest son was the direct victim of my experiments. . . .

(*Harijan* 18.8.1940: 253–54; quoted in Gandhi 1961, vol. 1: 378)

This is not the place to go into details, but the general point is of importance: to stress Gandhi's exemplary moral character runs counter to his own perception and tends to force discussion away from his phenomenal achievements and their relevance today.

Discussion is also diverted from central issues when it is said that strong, nonviolent action presupposes a personal belief in God. Especially among socialists, one finds atheism highly esteemed, and people are mindful of Lenin's implacable fight against religion. What they forget is that Gandhi fought godlessness, not atheism. "You may call yourself an atheist, but so long as you feel akin with mankind you accept God in practice."¹ His prayers were self-directed and not childish begging. He called himself an "orthodox Hindu," but this very orthodoxy he interpreted more widely than anybody else, including under Hinduism the teachings of Jesus and Mohammed and treating Buddha as the great, inestimable reformer of Hinduism. His religiousness was revolutionary, of a sort that if it is crushed, then mankind is lost. "You believe in some principle, clothe it with life. . . . I should think it is enough" (*Harijan* 17.6.1939). The pervasive occurrence of the term *God* in the speeches and writings of Gandhi should not discourage any serious atheist or agnostic. Even a cursory study of the use of this word in religious contexts reveals its pragmatic and performatory, rather than purely descriptive, character.

Many of Gandhi's political opponents have maintained that it was difficult to bring him to the realization that he had made a mistake when he was convinced he had not, but even those criticisms do not detract from the sincerity of Gandhi's own declarations of imperfection. He saw then, as clearly as we can with hindsight, how uninhibited idealizing came to play a fateful role for him. We can see this process by distinguishing three separate phases in his relationships with his supporters. In the first phase the re-

lationship can be expressed as the attitude “We won’t manage any better with him, but it would be unwise to shake him off”; in the second, as “Together with him we’ll certainly manage”; and in the third, as “He’ll manage *for us*.” In the second phase, Gandhi achieved his best work; in the third, his contribution greatly diminished. A great cause, Gandhi reflects, “can only be injured rather than advanced by glorification of its leaders” (*Young India* 13.7.1921; quoted in Prabhu and Rao 1967: 12). His successes in that last stage came increasingly to be attributed to his own high moral attainments. He was already a saint, a demigod. It became all too easy for people to think, “Whatever he says or does can’t possibly have much to do with what I can do. I have no great moral ambition nor any special abilities; I can’t reasonably be expected to follow his example.” By thus becoming clothed in a mystique of remoteness and divinity, Gandhi’s words lost the special appeal they had when his prestige had not yet reached its peak.

People came to stress the morality, not the efficiency, of nonviolent campaigns. As a leader of the nation, Jawaharlal Nehru insisted, “I am not a Gandhi,” not a man of that lofty character. “Therefore,” he seemed to say, “I have to rely on arms and on other means that Gandhi despised.”

The case of Albert Schweitzer presents a parallel. Here we have a man of outstanding ability, the recipient of several doctorates, an eminent musician, missionary, theologian, and healer; how possibly could such a paragon inspire ordinary mortals to action? Excellence of this order seems more likely to induce amazement and reverence than friendly cooperation. It is quite different, of course, if the man next door goes off to Africa to start up a small hospital: knowing Jones as we do, we feel there are no real obstacles to our following in his footsteps, should we feel so inspired.

Gandhi was never able, moreover, to make it sufficiently clear to his supporters that a nonviolent army needs soldiers, not just a general. When the crowds pressed in on all sides to touch him, they did not come to listen to what he said or to work with him; they came for comfort. These occasions were among the few when Gandhi lost control and showed anger. (“It is not that I do not get angry. I do not give vent to anger” [*Harijan* 11.5.35; quoted in Prabhu and Rao 1967: 16].) With Gandhi, as with others, reverence for the man himself is a product of the literature that grows up around him, but this literature contains little support for the reverential attitude. The essential picture we get of Gandhi agrees less with that of his famous admirers than with his own.

GANDHI'S EXPERIMENTS

I have become literally sick of the adoration of the unthinking multitude. I would feel certain of my ground if I was spat upon by them. Then there would be no need for confession of Himalayan and other miscalculations, no retracing, no re-arranging.

(*Young India* 2.3.1922: 135; quoted in Prabhu and Rao 1967: 11)

To describe Gandhi as a moral genius, however, would not be altogether absurd if what we want to stress is his constructive imagination and uncommon ingenuity in finding and applying morally acceptable forms of political action. In this field, Gandhi was an Edison. He made incredible discoveries in the field of ethics and politics and showed how to apply those discoveries. This, rather than any high moral level of his own conduct, is the truly remarkable feature of his achievement. Personally, of course, he did continually exert himself to maintain a high moral standard, but many people do that without ever making a moral discovery, a contribution to moral thinking and practice.

Especially in the West, Gandhi has been described as an ascetic. This is inadequate. He lived in certain respects like his followers among the poor, but his modest consumption was motivated less by Indian ascetic ideas than by certain views on the healthy life.

The life I am living is entirely very easy and very comfortable, if ease and comfort are a mental state. I have all I need without the slightest care of having to keep any personal treasures. . . . I regard myself as a householder, leading a humble life of service and, in common with my fellow-workers, living upon the charity of friends. . . .

(*Young India* 1.10.1925: 338; quoted in Prabhu and Rao 1967: 4)

He was also influenced by the idea that a person devoted to a great cause cannot afford to use energy for other purposes.²

India has long traditions of ascetic exercises and austerities, the *tapas*. A *saṁnyāsīn* is a person who renounces the world, who abandons and resigns worldly affairs and often starves himself in the effort to reach higher levels of religious consciousness. Gandhi explicitly repudiates that he is or ever tried to be a *saṁnyāsīn*.

Gandhi earned the title *mahātman*, great soul, primarily because of the effect of his work. To understand this, we must see the difference between external and internal criteria of moral quality. Referring to external criteria, the

goodness of an act is judged relative to its consequences. Referring to internal criteria, on the other hand, the strength of one's will to do good, the inflexibility of one's good intentions, is what counts. In practical life, where it is primarily what people do that matters, we tend to measure moral value in terms of achievement, not intention; and for Gandhi, too, it was what was accomplished that mattered. Thus, when we judge him, we must bear in mind that from the practical viewpoint, great moral achievement need not presuppose a corresponding degree of personal morality.

It Works

Gandhi and his influence can be studied from many points of view. In the following chapters, we shall concentrate on his teaching, in particular on his direct instruction for group conflict. The first question, then, must be, What is most characteristic and highly developed in Gandhi's teaching? Perhaps we are inclined to answer immediately that it was his conviction that the use of violence against living, sensible beings is never morally warranted, that it always infringes valid moral principles. Accordingly, Gandhi's doctrine might be summed up in one commandment: "Thou shalt not use violence." However, such a commandment would be highly misleading. The essential and most important point in Gandhi's doctrine, taken as a whole, is not a principle or a commandment, but the working hypothesis that the nonviolent resolution of group conflict is a practicable goal—despite our own and our opponents' imperfections, nonviolent means are in the long run more effective and reliable than violent ones; and they should be trusted even if they seem unsatisfactory for the moment. He teaches that nonviolence is a practical method that we may, indeed must, adopt immediately and without hesitation in social, political, national, and international conflicts. Here Gandhi is talking to all of us, not mainly to politicians whose power is dependent on the opinions of others.

Understood in this way, the essential and most original aspect of Gandhi's teaching is his descriptive and explanatory account of man and of man's ability to resolve his own conflicts. In the realm of principles and metaphysics, Gandhi shows no remarkable originality.

Any systematic morality must base itself on a number of purely descriptive or causal assumptions, as well as on intuitive, normative notions.

GANDHI'S EXPERIMENTS

Indeed, it is often precisely the emphasis it puts on one or the other of these two factors that gives a moral view its distinctive stamp; generally the tendency is for systems to lean toward descriptive and causal characteristics rather than intuitive and normative ones. It is therefore not so remarkable that new working hypotheses and methods covering group action can have immense import morally and normatively. Let us see what this general feature of philosophical systems can tell us about Gandhi.

There is nothing very original in condemning violence; and in any case, Gandhi's condemnation of physical violence is considerably less radical and more qualified than that of many other moralists. The doctrine that violence and coercion against one's fellow humans are indications of moral poverty is to be found in the teachings of prophets, philosophers, and wise men as far back as historical records go. In fact, among the generally acknowledged moral leaders from the time of ancient China and India down to the present, the principle of nonviolence has been the rule, and the condoning of violence, even in defense, the exception. In ancient India, not only was vengeance condemned, but the commandment "Thou shalt not kill" was often extended to all animal life. However, alongside this one often finds pessimistically and fatalistically colored theories of human frailty and of man's inability to adhere strictly to such commandments. Evil nature and ignorance have usually been considered to be so deeply ingrained in man that general use of nonviolence in ordinary political and social struggle is thought to be impracticable, or else the principle of nonviolence has been associated with the view that nonviolent methods, even if the individual could and did employ them, would be ineffective in any significant social and political conflict. In our own culture, influential studies of mass psychology have similarly stressed the impulse to mass violence, even if conceding that, individually, men are peaceable enough.³ All of these theories espousing "it will not work" are clearly anti-Gandhian, for Gandhi's teaching in its essence and originality is the straightforward doctrine that it *will* work and that it can be shown to work. The proof of this for him lay in his own all-important "experiments."

It follows that the focus of our examination of Gandhi's thought must be centered on his view of man and man's possibilities, especially on his faith in the inexhaustible richness of ways of mass action without violence and in the practical possibility of influencing every individual and group

by the example of nonviolent conduct. That this is the correct approach should be clear if we first base our study on, among other things, an examination of the contributions Gandhi made at the time when he was forming his ideas, that is, on a study of his activities in South Africa.

If the originality of Gandhi's teaching lies in his account of what men are constitutionally capable of, what it is in man's power to accomplish, it would nevertheless be misleading to say that his teaching was mainly of a descriptive character; above all, Gandhi stressed man's duties. To UNESCO's inquiry about individual rights, Gandhi replied characteristically that primarily man has no rights, only duties. From the duties, the rights follow like spring follows winter.

Gandhi maintained that the key to his faith in nonviolence lay in his practical experience with men. Since he believed only in the truth of what he was able to test, we are in a position to test his own power of judgment by reviewing and examining as far as possible what his actual experience with men was.

So far, research on Gandhi has neglected to view his activity from this standpoint. Although we cannot attempt any very comprehensive survey here, what we can and will do is to describe briefly some of his experiments.

When the Boer War broke out in 1899, Gandhi, though his "personal sympathies were all with the Boers," felt that if he was to demand rights as a British citizen, it was his duty as such to participate in the defense of the British Empire (Tendulkar 1951, vol. 1: 63). He collected 1,100 comrades to form an ambulance corps. Although opposed initially, Gandhi was eventually able to convince the British to accept their services at the end of 1899. This was done only after great difficulty, however, since the British apparently thought his countrymen unsuited to carrying weapons, unsuited even to carrying stretchers on the battlefield, and hence consigned them to transporting dead and wounded behind the lines. However, Gandhi's men showed unexpected courage and were eventually accorded the "honor" of working in the front line. A few years later, during the so-called Zulu rebellion of 1906, Gandhi himself organized an ambulance corps, which brought him into contact with some Zulus who had been flogged by the British. He and his corps also took care of people who had received burns when the British set fire to villages. Had he chosen to, he could have written an account of his experiences that would have caused

GANDHI'S EXPERIMENTS

consternation and horror and have increased the bitterness and hatred that already existed. However, instead of inflaming negative feeling, Gandhi did all he could to improve relations between the British and the Zulus. Thus we see him at this early stage, a courageous and influential man, already looking for positive solutions to problems of bloody conflict.

Another instance is worth mentioning. Indians in South Africa had become embittered by a judgment of the Supreme Court in 1913 that the state was henceforth to recognize Christian marriages only. Indian mothers were thus considered unmarried unless married as Christians. As a consequence, political demonstrations by women, something quite exceptional at the time, broke out. Gandhi succeeded, however, in getting the women actively involved in a wider struggle by persuading them to undertake a long march to the mines; the miners were then persuaded to stop work and to join the protest. Indignation grew to a high pitch when the men's wives were thrown into jail with male criminals, but Gandhi did not exploit the negative feelings. He persuaded the miners that whatever they did, they must avoid the use of violence, and he urged them to recognize that they would best attain their ends by other means. The miners, between two and six thousand of them, marched resolutely into the Transvaal, completely avoiding the use of violence — despite repressive measures taken against them by the police and frustrations caused by privation and hunger.

This march strengthened Gandhi's belief in the ability of the common man to grasp the meaning of nonviolence. The marchers were wholly illiterate; far from belonging to any culturally enlightened section of the community, they were, on the contrary, neither peaceable nor meek by disposition, but oppressed men who, seething with anger, had joined together to oppose repression and the discrimination shown against them.

Another case is even more illuminating. When a violent railway strike broke out that caused the government to declare martial law, Gandhi's own campaign had not been progressing very well. Now, suddenly, the government's own position was endangered, and Gandhi held a very good card. Ordinary political strategy would dictate that he play this card, take full advantage of the situation, and enlarge the immediate goals of his campaign. However, all Gandhi did was to enunciate once again his aims, adding that he had said that his goal, as it was then and as it had been, was to bring about the end of racial discrimination. The railway strike could not help

to persuade the opposition of the justice of his goal; quite the contrary, if Gandhi's forces were now to make use of the difficult position of the government to push through their demands, they should have done so without persuading their opponent of the justice of the Indians' cause.⁴

Gandhi broke off his campaign until the strike ended. In the long history of political strife, this event must surely have few parallels. The impression it made was profound. Gandhi's opponents saw that he and his followers literally meant what they said when they claimed, "This and only this is our aim in this struggle." By not exploiting their advantageous position, Gandhi's supporters remained true to his and their own aim, which was future cooperation with those who were then their opponents. He was able to draw his own conclusions from the effect made by such a plea for moderation.

If Gandhi had written a psychology of the masses, it would, no doubt, have been quite different from those that equate mass man with the aggressive coward, for he had seen with his own eyes how the masses are capable of being led to two extremes — on the one hand, to the most horrifying violence, and on the other, to the most inspiring kind of nonviolence. Gandhi invites us all to continue *experimenting* with nonviolence, and to see for ourselves what can be achieved.

Empirical Basis of Nonviolent Extremism

The combination of courage, sacrifice, and devotion to humanity shown by Gandhi does not significantly distinguish him from many thousands, even millions, of forgotten men who, in the course of history, have shown similar moral qualities. "The world knows so little of how much my so-called greatness depends upon the incessant toil and drudgery of silent, devoted, able and pure workers, men as well as women" (*Young India* 26.4.1928: 130). Perhaps the greatest moral heroes of all time have slipped by unknown and unacclaimed, or at least unrecorded. This may be true, but let us remember that Gandhi's experiments are not mentioned to illustrate any exceptional level of morality. Moral evaluations, at least those speaking of courage and so forth, assume insight into another person's motives, and motives are notoriously elusive. We invite the reader to study Gandhi's "experiments with truth" *within group conflicts* and apart from any opinion about their moral

GANDHI'S EXPERIMENTS

value. As I have already remarked, it is on the field of practical principle and action that our interest in Gandhi's teaching on conflict must mainly focus, not on the moral quality of his individual acts.⁵

It was Gandhi's claim that the greater the efficiency he acquired in the use of nonviolence, the greater the impression nonviolence made on his opponents. This claim he held to be a legacy of his experiences in South Africa. Was he right in this? Did his claim follow, according to inductive principles, as a valid conclusion from what he observed?

The railway strike episode and others of a similar kind did in fact provide Gandhi with an empirical basis for the hypothesis that the more he applied, even to fanatical extremes, the principle of nonviolence, the greater was its effect, and that every increase, no matter how slight, in the purity of the application of the principle meant an increase in the chances of success. Thus we can see what was meant by Gandhi's seemingly extreme claim that if one man were able to achieve an entirely perfect, nonviolent method, all the opposition in the world would vanish. Yet we must be careful to note that Gandhi explicitly stated that we are all more or less imperfect, not least himself, and that therefore we can talk only in terms of degrees of success and not perfection.

Gandhi, then, had a substantial experimental basis for his claim that the consistent, or pure, forms of *satyāgraha* (strictly, "method of holding on to truth") are more effective than the less consistent, or less pure, and that an increase in consistency or purity is especially favorable when a struggle is already well advanced. He had, in other words, an argument for nonviolence over and above the purely moral one, and this argument is strongly empirical and utilitarian. It may not seem so strange, then, that the versions that Gandhi's opponents gave of the political struggle in South Africa agree with his own, for where nonviolence was at once most consistent and effective, no side suffered from the struggle itself or from its outcome.

Gandhi's campaigns were fought in widely different environments. Only in South Africa were the numbers of people on his and on the other side small enough to make it possible for him to lead the campaigns personally. The opposing groups were sometimes rather rough — the extremely violent Pathans being one of the groups he antagonized but eventually turned into cooperating friends. In South Africa and in India, he met the British Empire's colonial police and jailers. Blood flowed freely, but the high ad-

ministration was eager not to use extreme forms of terror. In the conflicts between various religious groupings, terror was extreme; here Gandhi and his helpers showed how nonviolent methods were able to bring huge riots under control. It has been objected that under Hitler, Gandhi's nonviolence would have been of no avail. However, the Jews could scarcely have suffered more than they did, and it is an open question whether active nonviolent resistance would not have reduced the suffering and number of deaths. No leaders were trying out ways of resistance adapted to the special features of the German situation. From an empirical point of view, it is therefore of little value to discuss the consequences of nonviolent struggles in the Fascist and National Socialist areas.

When judging Gandhi's influence by the standards he himself set for empirical adequacy, we must subject it to the same rigorous critical scrutiny that we apply to any piece of social research. We should, however, also note the enormous complexity of Gandhi's experiments compared with ordinary experiments in, say, social psychology. The number of unknown, or insufficiently known quantities is overwhelming—so much so, in fact, that no conclusions can really claim the title of "scientific." Nevertheless, not all worthwhile research need culminate in well-founded scientific conclusions, nor need the unavoidable uncertainty of a conclusion cause us to reject it.

What then is our verdict to be? Judging from the material available to us, I think we may agree with Gandhi that his approach did in fact work and that the positive results of his action can to a large extent be traced to the nonviolence that characterized his campaign. If we look at nonviolence as a *working hypothesis*, the conclusion that nonviolence can be a vital force in resolving conflicts appears to be a valid inference from the experiments in which Gandhi was involved, however few and scattered these operations were.

Moralism and Pragmatism

Gandhi's writings and speeches are full of moral injunctions and exhortations. He was forever moralizing. That this did not depress those around him seems to be due to his humility, cheerful disposition, and profound sense of humor. "If I had no sense of humour, I should long ago have committed suicide" (*Young India* 18.8.1921: 238). Before that he might have been murdered!

GANDHI'S EXPERIMENTS

When reading the moralizing speeches, one's first impression is that Gandhi is severely curtailing political action: do *not* do this, do *not* do that. The promise to use only nonviolent means might seem tantamount to caring rather little for the aim and subordinating it to moral exercise. However, there is no known case in fifty years of fighting in which Gandhi states that although an aim could be reached more easily or more thoroughly through some measure of violence, one ought to remain nonviolent. He never gave expression to the view that a *satyāgraha*, or any part of a (genuine) *satyāgraha* was less effective than an alternative involving violence. Thus, every conclusion in the form of a moral prescription had a nonnormative equivalent. That is, the conclusion could be reached from premises of a purely instrumental character, lacking any moral ingredients.

If the reader suspects that this is only a sort of argumentational sleight of hand, it may be because he is unaware of the multiplicity of and different kinds of aims that a given political action is intended to help realize. A plan to murder someone or a plan to support a false rumor has an immediate objective of little or no intrinsic importance. It is the widespread indirect effects of such actions that count. If certain effects of an action obviously occur only through violence, Gandhi turns our attention to other effects that can hardly occur except by nonviolence. This example suggests how Gandhi never *needed* to rely on moral principles but could always argue empirically and pragmatically.

"Would you recommend nonviolence even if the world were such that it could not succeed?" This kind of question Gandhi never answered very clearly, it being in his opinion based on a contrary-to-fact hypothesis.

One may say that Gandhi had, or found himself committed to, a definite political ethics. Having said this, however, one must add, first, that the definiteness had limits: if one tries step by step to make the normative formulations more precise, to eliminate borderline cases, and to cover all kinds of hypothetical cases, it soon becomes clear that the implications of Gandhi's actions and speeches do not solve all dilemmas.

Second, one must add that the commitment to a definite political ethics does not imply the abdication of "the gentle inner voice." The ethical system can at most only codify or systematize past ethical decisions. No new decision follows from it. Each new decision, and each repetition of a kind of decision made earlier, must rest on the free reflection and deliberation of the subject. The system may help to make clear the interconnection

of past decisions, and the implications for the present, if one follows the same rules and uses the same hypotheses.

All of this will become clearer when we discuss definite norms and hypotheses in chapter 3. Here it is our aim only to clarify the nature of our approach to describing that part of Gandhi's political ethics that covers behavior in group conflicts.

Taking Gandhi to be a sender of norms, who is the intended receiver? The primary group of receivers were the listeners to his speeches and the readers of *Young India* and *Harijan*. Much was explicitly aimed at the British, and Gandhi often expressed his wish to reach a world audience, calling attention to what was happening in India. The more special norms can only be understood by describing special situations in India and South Africa, but adequate formulation must be such that the claim to universality is apparent. However dependent upon local circumstances, including the level of nonviolent training of the campaigners, Gandhi, like Hume, Kant, and others, conceived ethical norms as having a universal validity. Under certain sets of circumstances, certain kinds of behavior in conflict are timelessly right, others wrong.

For Gandhi, as for others who act in political life, there are questions of strategy and tactics. Some find a contradiction here. However, the timing of a campaign and all the measures and countermeasures must be chosen in harmony with hypotheses concerning causes and effects. Cleverness is necessary. The norms and hypotheses of nonviolence apply to strategy and tactics, but if Gandhi is right in his hypotheses, they never rule out the use of effective means. No effective tactical moves are ruled out. The norms do not introduce any limitations in that respect.

This point, like many others, reminds us of the fundamental function of *factual hypotheses* in Gandhi's ethics. Sometimes an ethics is conceived as a set of norms without any descriptive components. There is, however, no instance of an ethics that is capable of adequate formulations but contains no ordinary declarative sentences.

In what follows, we make extensive use of Gandhi's own explicit reasonings in the description of his ethics. Therefore, his many norms have unavoidably colored our exposition. Nearly all of them could be eliminated in favor of nonnormative statements, for example, "If one's intention is to reach a certain goal, then this particular behavior is more effective than that behavior." Although sentences of this and similar kinds often do not con-

GANDHI'S EXPERIMENTS

form to Gandhi's own way of talking, they can be used to express the bulk of his teaching.

The extensive use of Gandhi's own lucid argumentation does not imply an underestimation of the obscurity and complexity of his imperfectly articulated, or even unconscious, motivations. Erik H. Erikson (1969) has recently delved into this latter realm. His findings confirm that the basic norms and hypotheses of Gandhi had deep psychological roots in his character.

II

The Metaphysics of *Satyāgraha*

Truth

Absence of Theology: Pragmatic and Agnostic Leanings

Any adequate account of Gandhi's ethics and strategy of group conflict must take account not only his most general and abstract metaphysical ideas, but also the religious content of his sermons. His basic ideas and attitudes influenced his concrete norms and hypotheses and his conflict *praxis*. His numerous public prayers were part of his political campaigns, his political campaigns part of his dealings with God.

As mentioned, Gandhi considered himself a Hindu. He gives a condensed characterization of his belief in Hinduism and his relations to other religions in his article "Hinduism" (*Young India* 6.10.1921). Yet, Gandhi found Truth in many religions and faiths, and this explains why his teaching on group conflicts has no definite theological premises. The passage quoted earlier elaborates: "You believe in some principle, clothe it with life, and say it is your God, and you believe in it. . . . I should think it is enough" (*Harijan* 17.6.1939).

Gandhi's view is well within the wide perspective of modern theological movements. According to the religious thinker Paul Tillich, there is a dimension of depth in being¹:

That depth is what the word *God* means. And if that word has not much meaning for you, translate it, and speak of the depths of your life, of the source of your being, of your ultimate concern, of what you take seriously without any reservation. Perhaps, in order to do so, you must forget everything traditional that you have learned about God, perhaps even that word itself.

(Tillich 1948: 63 f.)

Militant atheism in the traditional sense is thus fully compatible with theism in Tillich's sense, perhaps even a necessary condition. Gandhi refused to call the atheist social workers of India "godless." Tillich refuses to call militant traditional atheists "atheists." "He who knows about depth knows about God" (Tillich 1948: 63 f.). Hence, militant atheists know about God; hence, they are not atheists.

Many Hindus denied that Gandhi was an orthodox Hindu and rejected his interpretations of the sacred texts, but he did not give up his universalist tendency for that reason. "If I am a Hindu, I cannot cease to be one even though I may be disowned by the whole of the Hindu population" (*Young India* 29.5.1924: 175; quoted in Prabhu and Rao 1967: 116).

His discussion with the atheist social worker G. Ramachandra Rao ("Gora") gave Gandhi the opportunity to stress the distinction between accepting God in theory and accepting God in practice: "You may call yourself an atheist, but so long as you feel akin with mankind you accept God in practice."²

For Gandhi, it is a necessary and sufficient condition for the truth of the sentences "N. N. believes in God," "N. N. accepts God," "N. N. believes in the existence of God," and "N. N. is not godless" that N. N. lives and acts in certain ways. N. N. may never have used the term *God*, or N. N. may be a militant atheist — these characteristics are not among the decisive ones.

Holding that belief or disbelief in God could only be shown and tested in practice, Gandhi did not take Rao's professed atheism as proof of disbelief in God. Nor would he take professed theism as proof of belief in God.

One may say that Gandhi accepted a pragmatic criterion, an action-oriented criterion, of truth for sentences like "God exists." He has no ontological conception of God such that those who believe that God has or does not have certain properties believe in God and those who believe he has or does not have certain other properties do not believe in God.

As to the certainty of our (intercultural) knowledge about God, Gandhi was largely an agnostic and stressed our limited powers of understanding. "God is the undefinable 'something' that we shall follow but do not know" (*Young India* 5.3.1925). He makes a distinction between God as worshiped and sought and God as the object of our thoughts and reflections. It is the former that counts.

*Multiple Use of Language: To Inform,
Convince, Preach, Agitate*

Gandhi was a great religious preacher, but in his sermons he combined preaching with ordinary factual information and political debate. There is no way of clearly separating the various uses of language. It is not possible, for instance, to separate performative uses of various kinds from cognitive uses. The term *God* mostly occurs in sentences that clearly exemplify performative religious uses, but it also occurs in sentences or is connected with sentences of ordinary cognitive use.

Religious uses are exemplified by passages like the following: “God is conscience. He is even the atheism of the atheist. For in His boundless love God permits the atheist to live. He is the searcher of hearts. He transcends speech and reason . . .” (*Young India* 5.3.1925: 81; quoted in Prabhu and Rao 1967: 49).

If one lists together some of the vast number of sentences of the kind “God is such and such,” it seems clear that it would be misleading to apply the principle of contradiction and other rules covering ordinary cognitive speech. In what follows, we shall quote and use religious sentences without any attempt to clarify to what extent they are intended to have a cognitive function. They may have none.

The latter solution is compatible with the trend to separate holy texts, such as the Bhagavad Gita and the New Testament, from organized religion.³ It elaborates and makes cognitive, whereas inspiration from the writings may be acognitive and noninstitutional.

The use of the terms *truth*, *Truth*, *truthful*, and so on, is bewildering in Gandhi’s speeches and writings, but this has to be expected considering the incompatibility of his aims both to be understandable to everybody and to convey deep thoughts inspired by complex metaphysical views. He studied Hindu philosophical works throughout his life, and his terminology in part reflects that reading. We cannot, however, expect a high level of doctrinal consistency. He was not a professional philosopher and claimed no profound erudition. Further, he tried in his speeches to be at once a preacher, an agitator, a politician, and also a reliable informer of facts. This furnishes one more reason for not worrying too much about inconsistencies on the purely verbal, cognitive plane. In what follows, we shall present the reader

with some of Gandhi's most important sayings relating to truth (in various meanings), starting with the relation between God and Truth.

Vast metaphysical or theological jungles may grow from words uttered without the slightest attention to meaning, whether metaphysical, philosophical, or scientific. To educate oneself in nonviolence, one must keep this in mind when reading Gandhi's exhortations. Consider these two pieces of autobiography touching the key terms *God* and *Truth*:

When a child, my nurse taught me to repeat Ramanama whenever I felt afraid or miserable, and it has been second nature with me with growing knowledge and advancing years.

(*Harijan* 17.8.1934: 231; quoted in Prabhu and Rao 1967: 80)

Though my reason and heart long ago realized the highest attribute and name of God as Truth, I recognize Truth by the name of Rama. In the darkest hour of my trial, that one name has saved me and is still saving me.

(*Harijan* 18.3.1933: 6; quoted in Prabhu and Rao 1967: 80)

The use of language exemplified by the repetition of *Rāmanāma* is central in religious incantations. Incidentally, *Rāma* was the only word Gandhi uttered when he was assassinated. To say it means or names God, a metaphysical entity, or that it signifies Truth, is misleading.

Truth and God

I claim to know millions. All the 24 hours of the day I am with them. They are my first care and last, because I recognize no God except the God that is to be found in the hearts of the dumb millions. They do not recognize His presence; I do. And I worship the God that is Truth or Truth which is God through the service of these millions.

(*Harijan* 11.3.1939: 44)

We believe—and I think it is the truth—that God has as many names as there are creatures and, therefore, we also say that God is nameless and since God has many forms we also consider him formless, and since He speaks to us through many tongues we consider Him to be speechless and so on. . . . I would say with those who say God is Love, God is Love. But deep down in me I used to say that though God may be Love, God is Truth, above all. . . . But two years ago I went a step further and said that Truth is God. You will see the fine distinction between the two statements, viz. that God is Truth and Truth is God.

(Quoted in Gandhi 1961, vol. 1: 10–11)⁴

The meaning of these statements becomes clearer if we compare them with the following passage, in which Gandhi says that he *worships* God as Truth only. Insofar as God is proclaimed to be something beyond or apart from Truth, Gandhi does not worship God:

There are innumerable definitions of God, because His manifestations are innumerable. They overwhelm me with wonder and awe and for a moment stun me. But I worship God as Truth only. I have not yet found Him, but I am seeking after Him. I am prepared to sacrifice the things dearest to me in pursuit of this quest. (Gandhi 1948: 6)

Philosophically, Gandhi here may be said to illustrate a conception of an immanent, not transcendent, God. There are as many definitions of God as there are manifestations. God is nothing apart from the particular creations, so he has “as many names as there are creatures” (*Young India* 31.12.1931; quoted in Prabhu and Rao 1967: 51). These are “his” manifestations, but not manifestations of something beyond or behind the creatures themselves. We may compare these formulations with Spinoza’s saying that individual beings are varieties of expressions of (the immanent) God. However, one should refrain from trying to pin down Gandhi’s utterances concerning God to any definite theological or philosophical conception.

Five Components of Gandhi’s Use of the Term Truth

Gandhi’s conception of Truth — with a capital *T* — may be said to have as many as five components, at least one of which is alive or operative in any definite occurrence of the term. Only in rare cases are all five components operative.

The first component is *ontological* and stems from the metaphysical identification of *truth* with “what really is,” “what can be said really to be, in the most exacting sense of being.” Gandhi refers in this connection to the meaning of the Sanskrit word *sat*,⁵ and he subscribes to the view that what undergoes change and has a component of passivity (being acted upon) has an inferior way of being.

A second component is *epistemological*. We all speak about beliefs and assertions being true if and only if they correspond with reality or the facts. *Factual correctness* is another term for truth in this sense. We may also use a

formula: “*S*” is true if and only if *S*, where “*S*” stands for a verbal expression of a belief or assertion.

There is also a *personological* component, *true* being another word for truthful, honest, genuine, and faithful as predicated of persons. The term *personological* is used instead of the more usual *psychological*, because the question “What is a person?” should be taken as a question more comprehensive than any question subsumable under a science of psychology. Truthfulness, genuineness, authenticity, and openness are today terms of psychological *and* metaphysical import. Gandhi sometimes uses *true* for a rather general concept of genuine, for example, “That economics is untrue which ignores or disregards moral values” (*Young India* 26.10.1924: 421; quoted in Prabhu and Rao 1967: 263).

A fourth component is *pragmatic*. Here Truth is identified with consistently acting selflessly (and therefore with consistent *abimsā*). Finally, there is a *religious* component, in which “the Truth” is used in the sense of the true Faith. These components are interwoven in many and sometimes obscure ways. Here we shall limit ourselves to a recommendation to remember the five ingredients when interpreting the expressions *true*, *truth*, *Truth*, and so on in Gandhi’s writings.⁶

In Gandhi’s terminology, it is perfectly justifiable to ask whether it is true or not true that such-and-such things ought to or should be done. What we often formulate as questions about what is right, good, or correct, Gandhi mostly discussed in terms of what is true. Thus if he says that what is true for one person may not be true for another, we might rather say that what is right for one person to do may not be right for another.

Being an objectivist in ethics, Gandhi also applies the epistemological truth concept in reference to norms, prescriptions, and imperatives. They too may be true or false. This objectivism is well exemplified in quotations below. Gandhi has much to say on the criterion of truth, that is, on how we get to know the truth, stressing this question when it applies to prescriptions.

Truth “is what the voice within tells you” (*Young India* 31.12.1931: 427), but this formulation of the criterion is a crude simplification. The voice within must be cultivated by training of various sorts. However, even then, in spite of earnest, prolonged seeking, different individuals’ inner voices may be in conflict.

How do we decide then? Do we, notwithstanding this situation, have a single criterion? Gandhi at this point, like the Sceptics in their argumenta-

tion against the Stoics, argues against the existence of infallible criteria. There is no guarantee that we find the truth in any matter. However, continued selfless devotion in search of truth will make the seeker aware of errors and thus lead him toward truth.

Fallibility, Pluralism, and Scepticism (Zeteticism)

Terrifying internal conflicts in India culminated in 1947 with the creation of two hostile states threatening each other with military invasion. The tragedy has as its metaphysical background the rejection of Gandhi's insistence on fallibility of judgment, the belief in historical necessity, and the deadly grip of a self-righteous refusal to reexamine conclusions.

Some quotations will make Gandhi's thinking on these issues clearer:

Sacrifice of the lives of others cannot be justified on grounds of necessity, for it is impossible to prove necessity. . . . One good reason for non-violence is our fallible judgment. The inquisitors implicitly believed in the righteousness of their deeds, but we now know that they were wholly wrong.

(*Young India* 21.5.1925)

It [*satyāgraha*] excludes the use of violence because man is not capable of knowing the absolute truth and, therefore, not competent to punish.

(*Young India* 23.3.1921)

The golden rule of conduct . . . is mutual toleration, seeing that we will never all think alike and we shall always see Truth in fragment and from different angles of vision. Conscience is not the same thing for all. Whilst, therefore, it is a good guide for individual conduct, imposition of that conduct upon all will be an insufferable interference with everybody's freedom of conscience.

(*Young India* 23.9.1926; quoted in Prabhu and Rao 1967: 420)⁷

Gandhi believes in the plurality, not the relativity, of conscience. The difference is fundamental. If some say "There is but one color, red," and I oppose this dictum by saying that there are a variety of widely different colors, I am not submitting to a "relativism of color perception." I have asserted plurality, not relativity. Similarly, in an ethically relevant situation, the dictum of conscience is not one in content, but a spectrum of distinct, often opposite, dicta. What a person asserts to be the only correct way of acting according to conscience Gandhi takes to be an expression of opinion. The truth of an as-

sertion of the kind “The only correct way to act is so and so” may be untestable from a practical standpoint, because my conscience dictates to me as an individual, not to mankind in general.

What . . . is Truth?

A difficult question . . . but I have solved it for myself by saying that it is what the voice within tells you. How, then, you ask, [do] different people think of different and contrary truths? Well, seeing that the human mind works through innumerable media and that the evolution of the human mind is not the same for all, it follows that what may be truth for one may be untruth for another, and hence those who have made these experiments have come to the conclusion that there are certain conditions to be observed in making those experiments. Just as for conducting scientific experiments there is an indispensable scientific course of instruction, in the same way strict preliminary discipline is necessary to qualify a person to make experiments in the spiritual realm. Everyone should, therefore, realize his limitations before he speaks of his inner voice. (Young India 31.12.1931: 428)

The inner voice is supreme as source, but the need for its purification (*brahmacarya*) is unlimited. The direction of its impulses may differ radically according to differences in past experiences and the internal and external situation. Gandhi thus has a short but forceful formula for explaining the source of an inescapable pluralism of views in ethics, politics, and all other realms in which human minds turn against each other. It is clear that Gandhi’s conception of antagonisms as springing from plural, contradictory views is radically different from a conception in which different views stem from faults, negligence of clear truth, evil intentions, and so forth. Consequently, efforts to eliminate antagonisms will also differ from those conceived as crusades against wicked people. What may be truth for one may be untruth for another.

The mind of the social reformer or revolutionary has, of course, also gone through a definite evolution and works through definite media; there is therefore need for preliminary investigations and soul searchings before entering a conflict. This in turn presupposes mental discipline.

But how is one to realize this Truth, which may be likened to the philosopher’s stone or the cow of plenty? By single-minded devotion [*abhyasa*] and indifference to all other interests in life [*vairagya*]—replies the Bhagavadgita. In spite, however, of such devotion, what may appear as truth to one person will often appear as untruth to another person. But that need not worry the

seeker. Where there is honest effort, it will be realized that what appear to be different truths are like the countless and apparently different leaves of the same tree. Does not God Himself appear to different individuals in different aspects? Yet we know that He is one. But Truth is the right designation of God. Hence there is nothing wrong in everyone following Truth according to his lights. Indeed it is a duty to do so. . . . (Gandhi 1957: chap. 1)

In such selfless search for Truth nobody can lose his bearings for long. Directly he takes to the wrong path, he stumbles and is thus redirected to the right path. Therefore the pursuit of Truth is true *bhakti* [devotion]. It is the path that leads to God. (Ibid.)

According to the Bhagavad Gita, each person has a definite path to pursue (*svadharma*, *svamārga*). It may eventually lead two persons or groups to kill each other. The main thing is to follow or express what one is convinced is the truth. Loss of bearings is not loss of insight in one truth common to all, but a person's insincerity or weakness in pursuing the truth according to "his lights." The disagreement with others need not worry the seeker.

Disagreement may persist, and has persisted, in spite of immense efforts to reach agreement. If, therefore, a successful search for Truth implied arriving at one opinion—one ethical, political, or religious conception—there would be few examples of success. If, however, it means searching for and following one's own light, the inner voice, success according to Gandhi is normal, provided the search is intense and persistent.

God is, because Truth is. We embark upon the search because we believe that there is Truth and that it can be found by diligent search and meticulous observance of the well-known and well-tried rules of the search. There is no record in history of the failure of such search. (*Harijan* 21.9.1934)

In order to be consistent with the frequent sayings of Gandhi that he is always on the way to and has never entirely reached Truth, the above use of *Truth* may be interpreted in the direction of truthful, trusting action in accordance with one's conscience or, in Kierkegaard's terms, as subjective truth, truth for me. "[M]an, a finite being, cannot know absolute truth" (*Harijan* 7.4.1946: 70; quoted in Prabhu and Rao 1967: 45). "Relative truth is all we know. Therefore we can only follow the truth as we see it" (*Harijan* 2.6.1946: 167; quoted in Prabhu and Rao 1967: 45).

What is true to me, my path, is not invariable, and fallibility also covers personal truth. Therefore your opponent is not only a potential follower of you, but you are also a potential follower of your opponent. There is no ending to this except death. The Gandhi scholar has expressed this point very well:

Never once, during my lifelong association with him did I hear from his lips an uncharitable expression or a harsh judgment about any of his opponents, critics or even maligners. It was not forgiveness but whole-hearted acceptance on his part of their standpoint as *their* truth, which might one day become also *his* truth.⁸

(Pyarelal 1956, vol 1: 10)

Gandhi sometimes accepts the norm “Forgive!” but strictly speaking, his theory of fallibility is such that one cannot know who ultimately should forgive whom.

It has sometimes been maintained that Gandhi held his own judgment to be infallible. On many occasions, certainly, he was stubborn, and even to very devout students he seemed not always to have admitted errors or inconsistencies. (He once paradoxically even made a virtue of inconsistency, but he was then clearly thinking of “inconsistency” in the sense of maintaining one conclusion at a certain date and a different conclusion on the same subject at an earlier or later date. This is, however, merely change of opinion and not inconsistency in the usual logical sense.)

On the whole, Gandhi showed a willingness to learn and to change his opinion when evidence seemed to him to require it. There is a wealth of interesting material supporting this in the annals of arbitration and, of course, also in the history of campaigns. Thus he first concluded that students should leave colleges to join campaigns of liberation, then later concluded that they should stay (being of more help when properly educated).

Another example: In May 1942, Gandhi announced that the British must go, must withdraw their troops from India immediately. However, in June, he changed his fallible opinion.

Abrupt withdrawals of the Allied troops might result in Japan’s occupation of India and China’s sure fall. I had not the remotest idea of any such catastrophe resulting from my action. Therefore, I feel that if, in spite of the acceptance of my proposal [to liberate India] it is deemed necessary by the Allies to remain in India to prevent Japanese occupation, they should do so. . . .

(Fischer 1943: 114–15)

In this instance Gandhi admitted his weak judgment, his failure to consider possible consequences of an action, and he reversed his opinion. More famous is the mistake he called his “Himalayan miscalculation”:

I am a humble but very earnest seeker after Truth. And in my search, I take all fellow-seekers in uttermost confidence so that I may know my mistakes and correct them. I confess that I have often erred in my estimates and judgments. As for instance, whereas I thought from insufficient data that the people of Kheda were ready for civil disobedience, I suddenly discovered that I had committed a Himalayan miscalculation and saw that they could not offer civil disobedience inasmuch as they had not known what it was to tender willing obedience to laws which might be even considered irksome but not immoral. Immediately I made the discovery, I retraced my steps. A similar error of judgment was committed by me when I represented what has been described as the Bardoli ultimatum. . . .

(*Young India* 21.4.1927; quoted in Gandhi 1961, vol. 2: 13)

But I am not aware of having changed my opinion about the necessity of killing certain dangerous animals in certain circumstances specifically mentioned in my articles. So far as I am aware of my own opinions, I have ever held the opinion expressed by me in those articles. That however does not mean that the opinion is unchangeable. I claim to have no infallible guidance or inspiration.

(Ibid.)

These quotations from Gandhi’s own writings and speeches might be summed up in the following way: it is ethically unjustifiable to injure an opponent if it is not verified that he is wrong and you are right. Now, it is always more or less unverifiable that he is wrong and you are right. Therefore, it is always unjustifiable to injure an opponent.

The carrying out of *satyāgraha* sometimes led to the injury of opponents. Even if this injury was unintentional, the *satyāgrahin* would, according to the above view, incur guilt. Gandhi did indeed feel that guilt.

The fallibility arguments quoted from Gandhi suggest that an agent might be justified in using violent means in a struggle, namely, when the agent knows with absolute certainty that he is right in both the norms and the hypotheses that form the basis of his decision to commit violence. It so happens, however, that all human beings are, and perhaps must be, incapable of *knowing* with perfect certainty. Nonetheless, Gandhi does seem to acknowledge that if knowing with perfect certainty were possible, then violence would in some cases be ethically justifiable.

These reflections show clearly that scepticism of the kind expressed by Gandhi is not sufficient to derive norms of nonviolence. Something must be added—for instance, the position that ultimately all life is one—so that the injury of one’s opponent becomes also an injury to oneself. Nothing would then be gained by violence even if one had the means to ascertain facts and justice absolutely.

The most highly developed philosophical scepticism is not that which denies the possibility of arriving at truth or knowledge, but the scepticism of Pyrrho, which requires the maintaining of a basic attitude of abstinence from final theoretical judgment (Zeteticism, zetetic Pyrrhonism). This *epoché*, or suspension of judgment, is consistent with action because theoretical certainty is not a necessary condition of action, even of forceful action. For Gandhi, similar views play a fundamental role in the ethical justification of nonviolence: how can we justify killing if, perhaps, our antagonist is nearer the truth than we are, or if there are two ways of seeing the matter?

Only God knows the whole truth, but since God is Truth, we arrive at the somewhat strange formulation “Only Truth knows the whole truth.” Gandhi comes close to such forms of expression:

The whole truth is only embodied within the heart of that Great Power—Truth. I was taught from my early days to regard Truth as un-approachable—something that one cannot reach. A great Englishman taught me to believe that God is unknowable. He is knowable, but knowable only to the extent that our limited intellect allows.

(*Harijan* 7.4.1947: 109; quoted in Prabhu and Rao 1967: 73)

In the light of the foregoing, it is not surprising that Gandhi characterized himself as a sceptic, an *anekāntavādin* (*Young India* 21.1.1926: 30). This complex term may be analysed into *an-eka-anta-vad-in*, a person who holds that there is more than one end, that is, more than one conclusion. It is an apt term for the ultimate pluralism of religious, moral, and political views compatible with human experience and reflection. Any human view is fragmentary and uncertain.

Gandhi read the Bhagavad Gita constantly and found in it the best support for nonviolence. He was also quite aware that opposite interpretations were possible. He recognized that he might well be killed by people who found it their duty, based on faith in the teachings of the same holy poem,

to kill a traitor. And to certain sects of Hinduism, because of his support of the Muslim minority, Gandhi was indeed the great traitor.

One of the two men sentenced to death in connection with Gandhi's murder in January 1948 was Nathuram Godse. "Godse had made a study of Bhagavadgita and knew most of its verses by heart. He liked to quote them to justify acts of violence in pursuing a righteous aim" (Khosla 1963: 218). Gandhi was in touch with these people and supported their claim to follow their conscience and their honest interpretation of the Bhagavad Gita.

After the first unsuccessful attempt on his life, Gandhi said at his prayer meeting:

[N]o one should look down upon the misguided youth who had thrown the bomb. [The youth] probably looked upon the speaker as an enemy of Hinduism. After all, had not the Gita said that whenever there was an evil-minded person damaging religion, God sent some one to put an end to his life?

(Tendulkar 1951–54, vol. 8: 331)

This is one of the clearest examples of Gandhi's belief in the plurality of incompatible views based on the voice of conscience. He would insist both that Truth was one and that men would never see it in the same way; and that we must accordingly live with irremediable conflicts and not take for granted that some dominant view comes nearer to the Truth than a minority view.

Truth, God, and Self-Realization

The Trinity of Realizations

We have started with an elucidation of Gandhi's use of the term *truth* and related terms. Search for Truth may be viewed as a fundamental principle or prescription in Gandhi's ethics. It is, however, inseparably connected with his conception of God, self-realization, and a variety of other central terms in Indian thought. Being a man of action and no great admirer of purely speculative thought, Gandhi introduces a simplification into traditional Indian metaphysics that is well worth mentioning. The way in which he does this shows a firm grasp of pragmatic thinking: "*To realize God,*" "*to realize the Self,*" and "*to realize Truth*" are three expressions for the same

development. “To realize God” is another expression for “to become like God” and “to face God.” The identification of this development with that of self-realization is clearly stated in, for instance, Gandhi’s highly interesting and original interpretation of the Bhagavad Gita:

Man is not at peace with himself till he has become like unto God. The endeavour to reach this state is the supreme, the only ambition worth having. And this is self-realization. This self-realization is the subject of the *Gita*, as it is of all scriptures. But its author surely did not write it to establish that doctrine. The object of the *Gita* appears to one to be that of showing the most excellent way to attain self-realization. That which is to be found, more or less clearly, spread out here and there in Hindu religious books, has been brought out in the clearest possible language in the *Gita* even at the risk of repetition.
(Desai 1946: 128–29)

The following excerpts support the same identification, and also simplify matters by adding the link to “liberation” (*mokṣa*, *mukṭi*).

What I want to achieve,— what I have been striving and pining to achieve these thirty years,— is self-realization, to see God face to face, to attain *Moksha*. I live and move and have my being in pursuit of that goal. All that I do by way of speaking and writing, and all my ventures in the political field, are directed to this same end!
(Gandhi 1927, vol. 1: xiv)

The denotational or extensional (not necessarily intentional or connotational) identity of “to find Truth”—if this is the same as “to realize Truth”—and “to become perfect” is plain from the following famous passage:

I am but a seeker after Truth. I claim to have found a way to it. I claim to be making a ceaseless effort to find it. But I admit that I have not yet found it. To find Truth completely is to realize oneself and one’s destiny, oneself to become perfect. I am painfully conscious of my imperfections, and therein lies all the strength I possess, because it is a rare thing for a man to know his own limitations.
(*Young India* 17.11.1921)

The Devotion of a Karmayogin

The practical aspect of the development is seen from Gandhi’s stress on action, his life as a *karmayogin*, a yogi of social action:

I do not know whether I am a Karmayogi or any other Yogi. I know that I cannot live without work. I crave to die with my hand at the spinning wheel. If one has to establish communion with God through some means, why not through the spinning wheel? "Him who worships me," says the Lord in the Gita, "I guide along the right path and see to his needs." My god is myriad-formed, and while sometimes I see Him in the spinning wheel, at other times I see Him in communal unity, then again in removal of untouchability, and that is how I establish communion with Him according as the Spirit moves me.

(*Harijan* 8.5.1937)⁹

In other words, the way of the Bhagavad Gita, the way of selfless action, is not a way leading up to a direct confrontation with God; it is itself the confrontation, provided the selflessness is consistent.

The same kind of pragmatic interpretation Gandhi attaches to the central notion of devotion:

A devotee may use, if he likes, rosaries, forehead marks, make offerings, but these things are no test for his devotion. He is the devotee who is jealous of none, who is a fount of mercy, who is without egotism, who is selfless. . . . We thus see that to be a real devotee is to realize oneself. Self-realization is not something apart.

(Desai 1946: 130)

In short, Gandhi identifies "to be maximally devoted" (or in his own words, "to be a real devotee")¹⁰ with "to live the life of selfless action," and as this is to face God, other pragmatic interpretations follow.

The expression "to be a real devotee," however, is apt to mislead a Western reader unfamiliar with Indian philosophy. The devotion is intimately connected with detachment. In most Western philosophy, the latter is associated with aloofness and indifference. The extreme detachment that Gandhi tried to develop throughout his life, however, is not aloofness. A central expression of this detachment is "indifference to the enjoyment of the fruits of action whether in this or in a future life" (Sanskrit: *ihāmutrārthaphalabhogavirāga*, here-and-yonder-action-fruit-enjoyment-indifference). We have a norm resembling this in Christianity, namely, "You shall not have regard for the fruits of your action." In Indian philosophy, detachment in this sense is intimately connected with political philosophy through the conception of active inaction. Perhaps the most important aspect of such detachment is a certain lack of regard for past failures that allows them to not

be viewed as determinants of future conduct or achievements. “Detachment enables one to overcome the effects of past faulty practice as well as handicaps of heredity and environment” (*Harijan* 7.4.1946: 72; quoted in Prabhu and Rao 1967: 463).

As Gandhi sees it, the importance of the combination of devotion and detachment is not to be underestimated: “A burning passion coupled with absolute detachment is the key to all success” (*Harijan* 29.9.1946: 336; quoted in Prabhu and Rao 1967: 464). Sometimes, however, Gandhi uses the term *passion* in such a way that every passion is by definition a passion *for the fruit of an action*. If passion is conceived in this way, then, detachment implies an absence of passion because the term *passion* includes passion for the fruit of an action.

To attain to perfect purity one has to become absolutely passion-free in thought, speech and action; to rise above the opposing currents of love and hatred, attachment and repulsion. (Gandhi 1948: 616)

The maximal development of detached passion and of devotion that springs from an identification with the universal Self is named *nirvāṇa* in some *ma-bhāyāna* Buddhist philosophies (Shcherbaskoi 1965). Although Gandhi was no philosopher, his thinking is nevertheless inspired by classical Indian philosophy.

From the above quotations and interpretations, it follows that according to Gandhi, the supreme intersubjective and intercultural goal of each individual is self-realization. Without some kind of concept of a self, however, the notion of a search for truth (in the epistemological and the ethical sense) becomes unintelligible. There must be someone who seeks and there must be something that he seeks.

The Self of Egotism and the Universal Self

Humility, Egotism, and Self-Realization

The term *humility* is used in many important connections in Gandhian writings, and not only to express “lack of arrogance or pride.” One sense seems relatively clear and acceptable to persons with different ideological backgrounds: a person lacks humility to the extent that he suffers from egotism (self-conceit). By “shedding the ego,” one then means shedding the

egotism. To reduce oneself to zero — a phrase often used by Gandhi — is accordingly to be understood as reducing the egotism-self to zero, that is, to eliminate it.

We prefer the expression “shedding the egotism” to “shedding the ego,” because the latter expression suggests a weakening of the resourcefulness or individuality of a person. The individual is “the supreme consideration” according to Gandhi, and certainly he should not be “shed.”

Egotism in the sense of self-conceit is present when, for instance, one is too proud and self-important to confess one’s errors, to retrace one’s steps. Without retracing steps, or learning from painful errors, however, one cannot find the truth, or at a minimum, the speed of the process is reduced indefinitely. It is understandable, therefore, that Gandhi maintains a good deal of humility (in the sense above).

One also has the duty to give advice or tell the truth even if it sounds arrogant, and therefore Gandhi frequently uses the phrase “in all humility.” It might mean something like “without pretending that I am more able than any other to tell what is true” or “without superiority or self-righteousness.”

The injunction to seek and follow truth results in fanaticism and violence only when the person who accepts the injunction has some form of superiority complex. One would not expect such a person, once he believes he has found the truth, to refrain from the oppression of deviants — for racial or other reasons. In fact, being nonviolent cannot really be regarded as an isolated trait, whether psychological or social. It must be studied as an aspect of a set of traits. This is clear from the way nonviolence is treated in the Bhagavad Gita; that is, as one virtue among others.

Gandhi finds support for his opinion that humility is necessary for truth-finding in the Bhagavad Gita, discourse 13, verse 7. He believes the virtues there listed to be conditions of insight, or even somehow aspects of it. He takes “freedom from pride and pretentiousness” to be equivalent to humility.

Here are two translations of verse 7:

Freedom from pride (*amānitva*) and pretentiousness, nonviolence (*ahiṃsā*), forgiveness, uprightness, service of the Master, purity, steadfastness, self-restraint (*ātma-vinigraha*).
(Translation by Gandhi)

Absence of pride and deceit, nonviolence, patience uprightness, service of a teacher, purity, steadfastness, self-control.
(Mascaró 1962)

In his commentary, Nataraja Guru says that *amānitva* (freedom from conventional pride) belongs “to a source different from society.” “A man concerned with his emancipation or self-realization is hardly concerned with what society thinks of him” (Guru 1961: 545–46).

Radhakrishnan says in his commentary:

It is clear from this list of qualities that jñāna or knowledge includes the practice of the moral virtues. Mere theoretical learning will not do. By the development of moral qualities the light of the ever changeless Self witnessing all but attached to none is discriminated from the passing forms and is no more confused with them.
(*Bhagavadgita* 1956: 305)

The gist of the matter is that there is something called “self” (*ātman*) that should be and can be reduced toward zero and something very different from this that should be and can be realized or cultivated maximally — and which is also called “self.” The latter, however, is mostly written with a capital *S*.

When the egotism-ego vanishes, something else grows, that ingredient of the person that tends to identify itself with God, with humanity, with all that lives. Therefore Gandhi may also say that once the reduction of one’s egotism-self is complete, one comes face to face with God, finds Truth, and realizes the universal self, the Self. The way of humility is essentially the way of reducing egotism.

There are other senses of *humility*, or other parts of a doctrine of humility. However, they seem more difficult to incorporate into a fairly generally acceptable ethics of group struggle. Thus, for Gandhi to have placed himself last among his fellow creatures would likely have taken unreasonable steps. Eating as little as the starving, or traveling as slow, would have rendered it impossible for Gandhi to fulfill his obligations. It was a duty, considering the importance of his work, to take care of himself more than many others and to enjoy many privileges. One may, of course, say that all this is consistent with placing oneself last among one’s fellow creatures — but only with considerable arbitrariness, it seems. Gandhi says that he will try to reach perfection even though he grants that no one has as yet reached it, and he thinks that he has practiced nonviolence more and longer than others just as he thinks he has a special or unique mission in India. In this and other respects, it is clear that Gandhi places himself before many others. However, we should not take this more or less realistic assessment of

the importance of his own personality to express a lack of humility. In what follows, therefore, we shall continue to interpret *humility* in the direction of “lack of self-conceit, egotism, or pride.”

Much of Gandhi’s activity, for instance in his campaigns in favor of higher wages for poor laborers, is directed toward a kind of egalitarian justice. It does not in any direct way aim at increasing the self-realization of the laborers in terms of their diminishing egotism. It must be taken for granted that what the poor laborers themselves, and other underdog groups, looked forward to reaching by victorious campaigns were goals acceptable to Gandhi, or at least not repugnant to him. Our conclusion, then, is that there are stages or phases on the way leading to maximal realization of the Self when it is justified or even necessary to fight against exploitation by others. Submission or self-extinction is no virtue. It is the submission and extinction of egotism that Gandhi proclaims.

What Gandhi accepted as goals for his campaigns can be subsumed under the heading of “self-realization,” in empirical, social scientific senses — and can include self-government in political science terminology. He wishes to contribute to *svarāj*, a set of conditions not directly defined by or correlated with absence of egotism. The modern Indian *svarāj* (anglicized to *swaraj*) derives from the Sanskrit *svarājan*, self-rule, self-command, lordship of the Self. Some of its connotations are not far from those of “self-realization.”

This concern of Gandhi for self-realization in the mundane empirical sense does not contradict his concern for realizing the big or universal Self, that is, for Self-realization. He seems to believe that increases in self-realization (in the empirical senses), insofar as they do not involve an increase in egotism, are favorable to the condition of Self-realization in the ethico-metaphysical sense. Such increases are neither necessary conditions for Self-realization nor sufficient, but favorable for the development of a personality adapted to the task of reduction of egotism. Not all goals are subservient to the fight against egotism — Gandhi was a man of many joys.

The Universal Self

In order to understand nonviolence as perfected by Gandhi and others, it is imperative to understand how *selfless* action is compatible with complete *self*-realization of the individual person. How can Gandhi say that to make oneself a zero is to realize oneself completely?

The answer, as suggested in the previous section, is that self-realization is conceived by Gandhi, together with a whole tradition of thinkers in the West as well as the East, as realizing not “oneself,” but “the Self.” This makes it necessary for us to elaborate on the concept of Self with a capital *S*. Its position in metaphysics is described well by the Indologist H. Zimmer:

The supreme and characteristic achievement of the Brahman mind (and this has been decisive, not only for the course of Indian philosophy, but also for the history of Indian civilization) was its discovery of the Self (ātman) as an independent, imperishable entity, underlying the conscious personality and bodily frame. Everything that we normally know and express about ourselves belongs to the sphere of change, the sphere of time and space, but this Self (ātman) is forever changeless, beyond time, beyond space and the veiling net of causality, beyond measure, beyond the dominion of the eye. (Zimmer 1961: 3)

Gandhi’s thought when approaching philosophical questions is close to that of Advaita Vedānta. In this system, the word closest to the meaning of *self* (with a small *s*) is *jīva*; to that of *Self* (with a capital *S*) is *Ātman* (with a capital *A*); to *God* in the writings of Gandhi, *Brahman*.¹¹ In his monograph on conceptions of self, Troy W. Organ says:

Liberation or salvation in Advaita Vedānta is self-realization. The process of liberation will usually begin when a person becomes disgusted with worldly life. At last there dawns upon a person the conviction that in his egoistic restlessness and clinging passions he is not moving in the direction of his highest values. He follows the path of self-knowledge until he attains a direct grasp of the unreality of the qualities of finitude and separation of the *jīva* and of the reality of infinitude and unity of *Ātman*. (Organ 1964: 109)¹²

It is characteristic of Gandhi as a *karmayogin* that he conceives the path of self-knowledge as the path of selfless action. That is, the discrimination between self and Self is fostered by reducing egotism toward zero — serving the suffering masses or in other ways as required by the social conditions confronting the yogin.

This makes it important to know how the Self (*Ātman*) is related to God and Truth. At this point, Gandhi may safely adhere to tradition: the Self somehow reveals itself both as God (*Brahman* in the old Indian tradition) and as Truth (*Sat*). Thus, there is no need for subtle differentiations so long as we follow Gandhi’s thinking. Self as *Ātman* corresponds to the notion of

the Absolute in Western thinking — something completely beyond ordinary description but somehow basic both to God and the World.

The Supreme Conceptual Bridge: From “Truth,” “self,” “Self,” and “Egotism” over “Essential Unity of Humanity” to “Nonviolence”

In conclusion, we may say that the self referred to in Gandhi’s term *self-realization* is the *Ātman*, what might be termed “the universal Self,” or “the great Self.” The self as an object of study in psychology and social science we might, in contrast to *Ātman*, call “the small self.” For the purposes of our systematization, we shall distinguish two components, the egotism and the nonegotism component of the small self. When reducing the egotism component toward zero, the faculty of orientation in the empirical world is not adversely affected. On the contrary, its functioning is perfected because pride (the main part of egotism) is an obstacle to truth seeking. The egotism-ego is therefore not the whole empirical self, but that component Gandhi has in mind when he says that we must reduce “ourself” to zero.

The metaphysics of Gandhi is such that he might insist, as he certainly suggests, that the process of reducing egotism to zero involves in practice (if not in theory) a process of understanding oneself and that in completing the process, one reaches complete self-realization (and thus “sees God face to face”). Thus, according to this branch or part of Gandhi’s metaphysics, reducing one’s own egotism to zero is a sufficient condition for complete self-realization. Degrees of self-realization and degrees of reduction of egotism may accordingly be taken to be the same. The world as seen by the increasingly self-realized person will be the world as seen by the decreasingly egoistic person. In order not to get into unnecessary metaphysical controversies, one may hold these equivalences to be extensional, not conceptual.

With increasing power of discrimination between self and Self, the universality of the Self is discerned. This leads to the conception of the essential oneness of all humanity. “I believe in the essential unity of man and for that matter of all that lives” (*Young India* 4.12.1924: 398; quoted in Prabhu and Rao 1967: 439). One’s own self-realization must therefore somehow include that of others. The requirement of helping the self-realization of others, “service,” and hurting no one, follows without further assumptions. The central place of this unity is well described by Pyarelal:

The rockbottom foundation of the technique for achieving the power of non-violence is belief in the essential oneness of all life. . . . The achievement of soul force depends on re-establishing our unity consciously with all psyches which manifestly exist beneath the threshold of individual consciousness and communicating that experience to others. (Pyarelal 1956–58, vol. 2: 792)

From causes of a psychological, social, and other kinds that are as yet little known, not a few people, from their earliest youth, perceive, apperceive, or feel a basic unity with and of all the human beings they encounter, a unity that overrides all the differences and makes these appear superficial. Gandhi was one of these fortunate people:

I have known no distinction between relatives and strangers, countrymen and foreigners, white and coloured, Hindus and Indians of other faiths, whether Musalmans, Parsis, Christians or Jews. . . . I cannot claim this as a special virtue, as it is in my very nature, rather than a result of any effort on my part, whereas in the case of *ahimsā* (non-violence), *brahmacharya* (celibacy), *aparigraha* (non-possession) and other cardinal virtues, I am fully conscious of a continuous striving for their cultivation.

(Gandhi 1948: 338; quoted in Prabhu and Rao 1967: 419)

To this may be added that people who have been haunted in their youth by a perception of their difference from others, of the essential hostility of strangers, suffer a formidable handicap. Service to mankind, nondiscrimination, and acceptance of extreme forms of egalitarianism are difficult to undertake or to tolerate when the basic perception of humanity is that of diversity and discord.

To facilitate the development of the feeling of kinship and unity must, according to the above, be a major concern of social policy. Thieves, to mention one example, should not be punished, according to Gandhi.

But whilst we may bear with the thieves, we may not endure the infliction. That would only induce cowardice. So we realize a further duty. Since we regard the thieves as our kith and kin, they must be made to realize the kinship. And so we must take pains to devise ways and means of winning them over. This is the path of *Ahimsā*. It may entail continuous suffering and the cultivation of endless patience.

(Gandhi 1957: chap. 2; quoted in Gandhi 1961, vol. 2: 26)

Also, one might add, it entails a decentralized society composed of small units — we must be able to get to know the thieves.

Such terms as “the universal Self” can scarcely be given experiential meaning without recourse to psychological and social processes of intense identification. They can be facilitated by the practice of yoga, but also by various kinds of voluntary social work as these are now carried out by dedicated people in many countries. The recent development in psychiatry and psychology favoring reciprocity in the therapist-patient relationship helps to make the identification easier.

There is an intimate relation between a belief in the ultimate oneness of all that lives and the belief that one cannot reach one’s own complete freedom without bringing about the freedom of others or remove all feelings of pain without relieving the pain of others.¹³

I do not believe . . . that an individual may gain spiritually and those who surround him suffer. I believe in *advaita* (non-duality), I believe in the essential unity of man and, for that matter, of all that lives. Therefore I believe that if one man gains spiritually, the whole world gains with him and, if one man falls, the whole world falls to that extent.

(*Young India* 4.12.1924: 398; quoted in Prabhu and Rao 1967: 439)

Gandhi’s tendency toward collectivism and egalitarianism is beautifully expressed in the following words:

A drop torn from the ocean perishes without doing any good. If it remains a part of the ocean, it shares the glory of carrying on its bosom a fleet of mighty ships.

(*Harijan* 23.3.1947: 78; quoted in Prabhu and Rao 1967: 440)

Synopsis

“To seek Truth” = to try to face God
= to try to realize the Self
= to try to reach salvation

Obstacle: Overpowering influence of sense impressions from which desires (infatuation) and egotisms arise. They hide the essential unity of one’s self with the universal Self and frustrate attempts at self-realization. Therefore:

“To try to realize the Self” = to try to act with detachment
= to try to act selflessly
= to act “without regard to the fruits of one’s action”

It involves trying to shed the egoistic component of the person.

On the other hand, the Self as “witness” in my person is the Self as “witness” in other persons. This is seen to the extent that the Self (i.e., its operation) is discriminated from the empirical self. The Self is seen as the essence of all persons, and self-realization, insofar as it involves the essence, involves self-realization of all. Therefore, a setback in self-realization or in the (material or spiritual) conditions of self-realization is a general setback for humanity. Hurting oneself is hurting others; hurting others is hurting oneself. Similarly, a gain is a general gain.

It remains to characterize selfless action: selfless action, if consistent, *is* being face to face with God, *is* actualizing the full essential identity with the Self, and *is* finding or embodying Truth. There is no transcendent God, Self, or Truth; they are immanent in the action. Furthermore, selfless action is action, intended to increase the general self-realization without special regard for any definite self, but starting with those who are worst off—the starving, exploited, subjected, and depressed.

Nonviolence

Himsā and Ahimsā: Broad and Narrow Concepts

The Sanskrit word *ahimsā* as applied in Indian philosophy has many meanings related in different ways to absence of violence, suppression, exploitation, and malevolence.

Occurrences of *ahimsā* in the Bhagavad Gita point to rather narrow concepts because the term is used for one single characteristic among a series of others. Compare, for instance, the enumeration of good qualities in discourse 13, verse 7, quoted on page 31. In this list, *ahimsā* occurs as one single good quality. It is not inappropriately rendered by “nonhurting,” “noninjuring,” “nonharming,” or “nonviolence,” but it requires a more specific meaning in relation to the other qualities. If a wider concept were intended, some of these others would only be parts or aspects of *ahimsā*, and it would be unnecessary or misleading to mention them on a par with it. Gandhi’s terminology is such that some of the other qualities listed would make up part of the connotation (intension) of *ahimsā*, while most of the others would be covered in its extension.

The general tendency in Gandhi's writings is toward equating *abhiṃsā* with all good qualities put together and *hiṃsā* with all bad ones. For example: because stealing is bad and nonstealing good, stealing tends to be taken to exemplify *hiṃsā* and nonstealing (as a principle), *abhiṃsā* (cf. p. 40). Several meanings may occur in the same paragraph: "It is not enough that there is no violence. A violent speech is often as injurious as a violent deed" (Tendulkar 1951–54, vol. 1: 331). In the first sentence, a narrow, physical concept is intended, a concept narrower than "injurious"—there are instances of injurious acts that are not violent. However, the adjective *violent* in "violent speech" has a different meaning. A violent speech is *not* taken to be a species of violence.

A taste of philology: *A-hiṃsā* is Sanskrit for absence of *hiṃsā*. The latter is correctly written *hiṃsā* or *hinsā* (harming, hurting, injuring) from the root *hiṃs* (harm, hurt, injure, slay). The word *hiṃ* may, in turn, have been a form of the verbal root *han*, which has a large number of meanings: strike, smite, slay, kill, destroy, dispel (darkness), and so forth. These meanings seem on the whole to be more predominantly physical than those of *hiṃs*.

Gandhi, in his application of the term, makes use of several of the meanings of *abhiṃsā*, and he adds at least two others: (1) *abhiṃsā* as a designation of his ethics of group struggle—in this sense, the term is a proper name for a doctrine or a closely related set of prescriptions and descriptions; (2) as a designation of actions or practice in accordance with *abhiṃsā* in the first sense.

Let us see what he himself says about the term:

Ahiṃsā means avoiding injury to anything on earth in thought, word, or deed.
(*Harijan* 7.9.1935: 234)

Adopting a wide interpretation of *injury*, the quotation exemplifies a very wide concept of *hiṃsā*: not avoiding injury to *at least one thing* on earth in thought, word, or deed. "Things" would include all living beings and perhaps also a selection of nonliving things. Destruction as part of sabotage is sometimes referred to as *hiṃsā* even if the things destroyed are not the property of anyone. To keep things we do not need, but which others might need is "injuring," that is, reducing certain chances that others may have for self-realization.

Non-stealing does not mean merely not to steal. To keep or take what one does not need is also stealing. And, of course, stealing is fraught with violence.

(Hingorani 1968: 5)

Under mental forms of injury, the wide interpretations include hurting people's feelings, hurting their dignity, and hurting relations between others or between others and oneself. The feelings and relations referred to must be positively valued. It would not be *himsā* if person *A* hurts the feelings of hatred harbored by person *B* or his own feelings of hatred toward *B*. Thus, the wide conception of *himsā* presupposes an ethics. Consequently, an adequate account of the notion of *himsā* implies an account of the ethics in which *himsā* is just one of many notions. As is usually the case in philosophical inquiry, we are led from consideration of a part to that of a total view.

As an example of a broad use of *himsā* (violence), the following is well known:

I cultivate the courage to die without killing, but for the man who does not have this courage I would wish him to cultivate the art of killing and being killed, rather than flee shamefully from danger. For he who runs away is guilty of mental violence: he flees because he has not the courage to be killed in killing.

(*Young India* 2.11.1920)

What the coward violates may be said to be a relation to himself, that of striving for self-realization. A more specific interpretation of the violence of the coward may be given, but our point here is mainly to establish that, used in the wide senses discussed here, the assertion "This is *himsā*!" does not say much more than "This is ethically bad!"

The concept of *ahimsā* made by negating the wide concept of *himsā* is correspondingly narrow. This has the important consequence that much is required of a struggle in order to be in accordance with *ahimsā*. The wider the concept of *himsā*, the narrower, of course, will be the corresponding concept of *ahimsā*. Considering the need for degrees of *ahimsā*, the narrow concept might be expressed by the term "perfect *ahimsā*." Such a grading is applied rather often by Gandhi. If we take "violence" and "non-violence" as conventional renderings of *himsā* and *ahimsā*, we will find that corresponding relations between the English words hold. In order to avoid misunderstanding, one might prefer to use the terms *nonviolence* and *nonviolent* without a hyphen to express high degrees of *ahimsā* — degrees required according

to the doctrine of *ahimsā*. The unhyphenated term *nonviolence* would then have a positive quality that is not well expressed by the simple negation, non-violence. Because this distinction would often not be noticed and because, unlike in Gandhi's era, contemporary usage eliminates the hyphen, even when communicating the simple negation, we shall not attempt to use the hyphen (or its absence) to make such distinctions.

It is sometimes useful to point out an ideal limit, however great or small the chances of reaching it. Gandhi may be said to refer to a "zero degree" of *himsā* and a "maximum degree" of *ahimsā*. Yet, he has made it amply clear that no one on this planet can help transgressing a norm expressible by "Avoid doing injury to anything in thought, word, or deed." The extension of the narrow concept as applied to persons is therefore strictly speaking zero — like the concept of an ideal gas or of "the economic man." As Gandhi points out:

Ahimsā means not to hurt any living creature by thought, word, or deed, even for the supposed benefit of that creature. To observe this principle fully is impossible for men, who kill a number of living beings large and small as they breathe or blink or till the land. (Gandhi 1961, vol. 2: 28)

It is not difficult to find instances in which Gandhi explicitly repudiates what he says here about *himsā* in relation to benefit. The following is a defense of euthanasia:

Non-violence sometimes calls upon us to put an end to the life of a living being. For instance a calf in the Ashram dairy was lame and had developed terrible sores; it could not eat and breathed with difficulty. After three days' argument with myself and my co-workers I had poison injected into its body and thus put an end to its life. That action was non-violent, because it was wholly unselfish inasmuch as the sole purpose was to achieve the calf's relief from pain. It was a surgical operation, and I should do exactly the same thing with my child, if he were in the same predicament. (Gandhi 1959: 44)

Much terrorism has perhaps been performed "wholly unselfishly," for instance, terrorism perpetrated by religious movements. Gandhi would not likely accept the postulate of unselfishness as sufficient for the qualification of nonviolence. Gandhi also subscribes to a graduated norm of minimizing *himsā*: to avoid as much as possible, and as often as possible, the injury of beings. Mostly, or perhaps always, he has living beings in mind, but recent

development of the movement against injury to nature may well find it adequate to subsume its basic norms under the above very general principle of *ahiṃsā*, either read as an imperative or as a valuation: it is of negative value to injure anything. This formulation conveniently points to the near vacuity of the principle as long as we do not explain how we define or would exemplify injury.

Another, still more severe conception:

[E]very act of injury to a living creature and endorsement of such an act by refraining from non-violent effort, whenever possible, to prevent it, is a breach of *ahiṃsā*.
(*Young India* 30.8.1928: 294)

This declaration so widens the concept as to make it an act of violence to *abstain* from efforts to prevent injurious acts, for instance, suppression, manipulation, and exploitation. Unjust societies are violent in this sense. Retreat to the dead regions of the Himalayas or the Antarctic does not avail: sitting there, you are violent if some preventable violence of the active or passive kind is taking place somewhere else. The width of the above conception depends on how widely we conceive the “possible”: you are violent if you do not prevent violence that it is possible for you to prevent. Taking “possible” in a wide sense, we get another zero-degree of *hiṃsā* and a maximum of *ahiṃsā*, useful as an indication of an ideal limit, but otherwise inapplicable.

When Gandhi, in his life as politician, declared that this or that was violence, he mostly had such narrower concepts of violence in mind. They must be placed somewhere between “crude malevolent physical violence” and “physical or mental injury, temporary or permanent.” What he had in mind in each instance cannot be found by looking at any definition or at general accounts of his views.

The study of the etymology or the various usages of *ahiṃsā* and the various concepts of *ahiṃsā* that Gandhi may have had in mind is of limited usefulness. It should not be neglected, but neither should it be taken to offer any key to the understanding of the immense complexity of Gandhi’s thought and action.

One may justifiably talk about “the political ethics of nonviolence (as conceived by Gandhi).” However, since Gandhi never attempted any systematization himself, his ethics can only be explicated in the form of a *hypothetical reconstruction*. If we consider the vast area of activity to which Gandhi

applied ethical valuations, it is not surprising that his ethics, if at all systematizable, must be immensely complex. There are no easy ways of deriving fairly concrete policies of action from the general and abstract, and often noncognitively expressed, basic rules or maxims of “nonviolence” as applied to political life. Gandhi himself clearly realized this difficulty:

There are problems of Truth, but it is not very hard to understand what Truth is. But in understanding Ahimsā we every now and then find ourselves out of our depth. Ahimsā was discussed in the Ashram at greater length than any other subject. Even now the question often arises whether a particular act is violent or non-violent. (Harijan 27.11.1949)

Some admirers of Gandhi insist that his ethics should not be systematized because no living ethics can be and because such an effect is foreign to his spirit. However, the intense and protracted discussion, favored by Gandhi himself, regarding whether this or that act is consistent with *ahimsā* furnishes a convincing refutation of the “irrationalists.” The important thing is to keep the pretensions of any rational reconstruction realistic, that is, at a rather modest level.

Gandhi on Nonviolence

After so much conceptual gymnastics, the reader ought to be rewarded by enlightening quotations from the Mahatma himself.¹⁴ They show the intended universal applicability, active character, and multifarious forms of nonviolence:

Ahimsā is not the crude thing it has been made to appear. Not to hurt any living thing is no doubt part of Ahimsā. But it is its least expression. The principle of Ahimsā is hurt by every evil thought, by undue haste, by lying, by hatred, by wishing ill to anybody. . . .

In its negative form, it means not injuring any living being whether by body or mind. I may not, therefore, hurt the person of any wrong-doer or bear any ill-will to him and so cause him mental suffering. This statement does not cover suffering caused to the wrong-doer by natural acts of mine which do not proceed from ill-will. It, therefore, does not prevent me from withdrawing from his presence a child whom he, we shall imagine, is about to strike. Indeed, the proper practise of Ahimsā requires me to withdraw the intended victim from the wrong-doer, if I am in any way whatsoever the guardian of such a child. . . .

Ahiṃsā really means that you may not offend anybody, you may not harbour an uncharitable thought even in connection with one who may consider himself to be your enemy. . . .

If we resent a friend's action or the so-called enemy's action, we still fall short of this doctrine. . . . If we harbour even this thought, we depart from this doctrine of ahiṃsā. Those who join the ashram have to literally accept that meaning. That does not mean that we practise that doctrine in its entirety. Far from it. It is an ideal which we have to reach, and it is an ideal to be reached even at this very moment, if we are capable of doing so. . . .

In its positive form, Ahiṃsā means the largest love, the greatest charity. If I am a follower of Ahiṃsā I must love my enemy. I must apply the same rules to the wrong-doer who is my enemy or a stranger to me as I would to my wrong-doing father or son. This active Ahiṃsā necessarily includes truth and fearlessness. As man cannot deceive the loved one, he does not fear or frighten him or her. Gift of life is the greatest of all gifts; a man who gives it in reality, disarms all hostility. He has paved the way for an honourable understanding. And none who is himself subject to fear can bestow that gift. He must therefore be himself fearless. A man cannot then practise Ahiṃsā and be a coward at the same time. The practise of Ahiṃsā calls forth the greatest courage. . . .

My reverent study of the scriptures of the world has led me to the belief that all register emphatic and unequivocal testimony in favour of non-violence being practised by all, not merely singly but collectively as well. In all humility I have often felt that having no axes to grind and having by nature a detached mind, I give a truer interpretation of the Hindu, Islamic or other scriptures. For this humble claim I anticipate the forgiveness of Sanatanists, Christians and Mussalmans. . . .¹⁵

Gandhi on Truth

Even at the cost of some repetition, we shall stress the relation between a nonviolent ethics of struggles and persistent disagreements and an honest unrelenting search for Truth.

The most famous dialogue on the relation between Truth and nonviolence is that between the Hunter Committee's council and Gandhi in 1919. Since the details of the dialogue, however well known, have still not sufficiently impressed all students of Gandhi, we find it justifiable to quote from it:

Council: However honestly a man may strive in his search for truth, his notions of truth may be different from the notions of others. Who then is to determine the truth?

- Accused: The individual himself would determine that.
- Council: Different individuals would have different views as to truth. Would that not lead to confusion?
- Accused: I do not think so.
- Council: Honestly striving after truth differs in every case.
- Accused: That is why the nonviolence part was a necessary corollary. Without that there would be confusion and worse.

The most crucial point is perhaps Gandhi's admission that "honestly striving after truth differs in every case." Such an admission makes it altogether natural to look at violent opponents, even terrorists, without moral indignation insofar as they are honest strivers after truth. Further, who is able to judge the degree of honesty of others? Gandhi's line of information and persuasion is firmly based on the admission of honestly held opposite views and of our high degree of ignorance concerning the efforts made by different people to arrive at facts or plausible hypotheses.

Highly significant are the following three central passages concerning the relation of *ahimsā* to truth:

The more I search after Truth the more I feel it is all-inclusive. Truth is not covered by non-violence. But I often experience that non-violence is included in truth. What a pure heart feels at a particular time is Truth; by remaining firm on that, undiluted Truth can be attained. This does not involve any conflict of duty or conscience either. But difficulties often arise in determining what non-violence is. The use of bacteria-destroying liquid is also violence. It is only by firm adherence to truth that one can live non-violently in a world which is full of violence. I can, therefore, derive non-violence out of truth.

(*Harijan* 27.11.1949)

In this quotation, the personological and pragmatic component of Gandhi's use of the term *truth* has gained the upper hand. The epistemological component has been submerged, and it is only this that makes it not too unlikely that nonviolence can be derived from truth. Mostly, Gandhi—as shown above—stresses the difficulty of finding truth and the inevitability of conflicting views. If there are opposite views about what is happening in a conflict, one may unintentionally injure one or both sides. A "pure heart" is not enough, as Gandhi often shows; one must try to reach a true opinion about what is going on.

It is perhaps clear from the foregoing, that without *Ahiṃsā* it is not possible to seek and find Truth. *Ahiṃsā* and Truth are so intertwined, that it is practically impossible to disentangle and separate them. They are like the two sides of a coin, or rather of a smooth unstamped metallic disc. Who can say, which is the obverse, and which is the reverse? Nevertheless *Ahiṃsā* is the means; Truth is the end. Means to be means must always be within our reach, and so *Ahiṃsā* is our supreme duty. (Gandhi 1961, vol. 2: 27)

Most of the components of the Truth concept are manifest in the following elucidation of the relation of Truth to nonviolence:

But it is impossible for us to realize perfect Truth so long as we are imprisoned in this mortal frame. We can only visualize it in our imagination. We cannot, through the instrumentality of this ephemeral body, see face to face Truth which is eternal. That is why in the last resort one must depend on faith.

It appears that the impossibility of full realization of Truth in this mortal body led some ancient seeker after Truth to the appreciation of *Ahiṃsā*. The question which confronted him was: "Shall I bear with those who create difficulties for me, or shall I destroy them?" The seeker realized that he who went on destroying others did not make headway but simply stayed where he was, while the man who suffered those who created difficulties marched ahead, and at times even took others with him. (Ibid., p. 25)

In short, the seeker after Truth understands that it never will be within reach, that he always will be more or less in untruth and error. This makes him nonviolent.

In our attempt to condense and systematize Gandhi's teaching on group conflicts, it has been necessary to cut out some of these themes relating to Truth and nonviolence. We have adopted the subordination of nonviolence to Truth, the latter notion split into two: truth with a small *t* and self-realization.

A Conceptual Reconstruction

Gandhi often speaks about realizing Truth and realizing God;¹⁶ he speaks somewhat more rarely of realizing self.¹⁷ He nevertheless maintains, as has already been mentioned, that "self-realization is the subject of the Bhagavad Gita as it is of all scriptures" (Desai 1946: 1). In order to condense the teaching and make it more universally understandable, the aspects of realization may be reduced to two: the search for self-realization or God or Truth with a capital *T* and the search for truth (with a small *t*).

From truth with a small *t*, or from the ontological or epistemological concept of truth, no *ahimsā* principle can be derived. One may, however, construct a derivation by taking “search for God or Truth” to be, in the main, other names for the more understandable self-realization and adding a metaphysical postulate announcing the essential or ultimate oneness of all living beings. From the premises that one should realize one’s self and that all (living) selves are ultimately one, the necessity of both truth seeking and *ahimsā* may be derived.

We now introduce the concept of an individual *P*’s self-realization as realization of *P*’s potential for complete expression. The actual level of self-realization attained may show variation and can never reach the theoretical maximum. There are different kinds of measures of level of self-realization. Therefore, when applied in the following, Gandhi’s criteria are presupposed. According to Gandhi, the path toward an individual’s maximum self-realization does not necessarily obstruct the paths of others; on the contrary, mutual aid is possible and desirable.

For the sake of our condensed conceptual reconstruction we shall now introduce a general concept of nonviolence:

Himsā (violence) is avoidable direct influence in the direction of a lower level of self-realization. *Ahimsā* (nonviolence) is direct influence in the direction of a higher level of self-realization.

According to Gandhi, a decrease or increase of self-realization in one individual involves a decrease or increase (not necessarily of the equal magnitude) of the self-realization of others.¹⁸ Thus, *himsā* by anyone against anyone is also *himsā* against me.

The main motive for introducing this broad concept of violence, and the corresponding narrow concept of nonviolence, is to allow us to subsume under this broad concept of violence all those phenomena that Gandhi actually does subsume. To put it more directly, we wish to subsume exploitation, suppression, and other phenomena that are best defined without reference to any person’s acting with manifest physical violence against another. Impersonal, structural, sociological phenomena that in an avoidable way decrease or obstruct the increase of self-realization are all subsumable under this broad concept of violence.

How Gandhi himself made such subsumptions will be clear later. Here we shall only recall his dictum that the essence of violence is exploitation and that an unjust law “is itself a species of violence” (Gandhi 1944, vol. 1: 150).

*Graphic Presentation of Principles and Norms:
Systematizations *E and *F*

In what follows, those principles and norms from which the norms and hypotheses of Gandhi's teaching on group struggle are explicitly derived are, first of all, made explicit and then fitted into a graphical presentation. There are, of course, many ways to present such derivations. The one offered here is called Systematization *E for easy reference.

SYSTEMATIZATION *E

- *N₁ ≡ Seek complete self-realization.
- *H₁ ≡ Complete self-realization requires seeking truth.
- *N₂ ≡ Seek truth (from *N₁ and *H₁).
- *H₂ ≡ All living beings are ultimately one.
- *H₃ ≡ Violence against yourself precludes realizing your self.
- *H₄ ≡ Violence against any living being is violence against your self
(from *H₂ and *H₃).
- *H₅ ≡ Violence by anyone against anyone precludes complete self-
realization of anyone (from *H₃ and *H₄).
- *N₃ ≡ Act so as to reduce and eliminate violence (from *N₁ and *H₅).
- *H₆ ≡ Your complete self-realization involves that of others (from
*H₂ and *H₅).
- *N₄ ≡ Act so as to help others in their quest for self-realization (from
*N₁ and *H₆).
- *N₅ ≡ Act so as to help others in their quest for truth (from *N₁, *H₁,
and *H₆).

The immense weight Gandhi attached to the term *Truth* in his speeches and prayers makes it important to try out a systematization with "realize Truth" as the formulation of the top norm. Systematization *F is such an attempt. It is clear, I think, that the systematization is unduly complicated and the derivations not as obvious, on average, as those of Systematization *E.

Figure 1. Graphic presentation of the norms and hypotheses of Systematization *E.

The reason for the shortcomings is to be found in Gandhi's multiple use of the word *Truth*.

The basic sentences "Seek complete self-realization," "Realize Truth," "Realize God," and "All are ultimately one" are intended to convey something that is prior to the distinction between an injunction and a description. The True and the Real in much philosophy from Rigveda to Bradley are not adequately thought of as a world or cosmos or anything existing here and there. There is a basic positive valuation of some sort that makes it not quite adequate to formulate the basic "norms" as prescriptions rather than descriptions. On the other hand, the formulation "All living beings are ultimately one," grammatically a description, has a prescriptive component. The oneness is something to be realized; it is not, rather, merely a fact.

The combined descriptive and prescriptive function of basic metaphysical utterances makes it unwarranted to accuse Gandhi of making the naturalistic fallacy. He does not, to take one instance, derive a norm ("Act non-violently") from a description ("All life is ultimately one"). The latter is a component of the metaphysical utterance concerning the universal Self, neither a prescription nor a description.

There are many ways in which Gandhi's ethics and principles of group struggle can be derived from his metaphysics. However, certain positions

THE METAPHYSICS OF SATYĀGRAHA

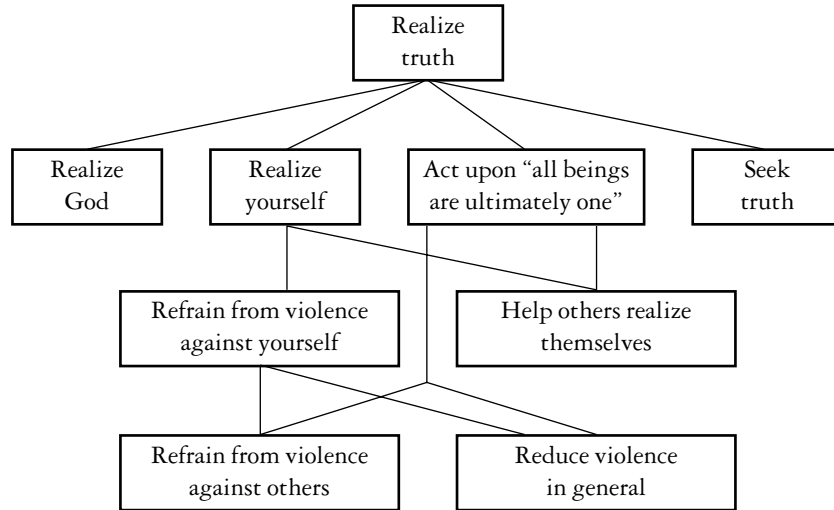

Figure 2. Graphic presentation of Gandhi's norms as depicted in Systematization *F.

must be considered central in any derivation: the ultimate unity of all life, the inescapable fallibility of ethical as well as factual judgments, and the close dependence of what can be achieved (the goals) on how we proceed to achieve it.

From the point of view of analytically oriented philosophy, the wording of Systematizations *E and *F is inordinately vague and ambiguous. Nevertheless, to take this as an objection suggests a misconception of the role of analysis. That role is eminently that of explication and making precise, taking the spontaneous and intuitive metaphysical utterances as initial formulations or starting points.

The formulations *E and *F are starting points for interpretations articulated with a higher degree of preciseness. Thus, "oneness of all living beings" might be made more precise by dynamic interpretations using the process of identification rather than the status of identity. Identification, again, might be considered as a psychological, a sociological, or a biological term, or it might be substituted by a combination of these aspects plus an ethical and political norm. Such substitutions are clearly made by Gandhi. In *Yeravda Mandir*, for example, the religious concept of sacrifice is identified by an ethico-political concept of work:

A Conceptual Reconstruction

The divine law, that man must earn his bread by labouring with his own hands, was first stressed by a Russian writer named T. M. Bondaref. Tolstoy advertised it and gave it wider publicity. In my view, the same principle has been set forth in the third chapter of the *Gita* where we are told, that he who eats without offering sacrifice eats stolen food. Sacrifice here can only mean Bread labour.—Reason too leads us to an identical conclusion.

(Gandhi 1957: 35)

The background of Gandhi's thinking is such that theology, metaphysics, and politics simply cannot be separated—neither in life nor in semantics!

III

Norms and Hypotheses of Gandhian Ethics and Strategy of Group Struggle

Introductory Remarks

Aim of the Systematization

Any normative, systematic ethics containing a perfectly general norm against violence will be called an ethics of nonviolence. The content will show variation according to the kind of concept of violence adopted. In order to do justice to the thinking of Gandhi, the term *violence* must be viewed broadly. It must cover not only open, physical violence but also the injury and psychic terror present when people are subjugated, repressed, coerced, and exploited. Further, it must clearly encompass all those sorts of exploitation that indirectly have personal repercussions that limit the self-realization of others.

The corresponding negative term *nonviolence* must be viewed very narrowly. It is not enough to abstain from physical violence, not enough to behave peacefully.

In what follows, we offer a condensed systematic account of the positive ethics and strategy of group struggle, trying to crystallize and make explicit the essentials. We use the adjective *positive*, because the systematization does not include a treatment of evils, for instance, a classification into greater and less great evils. (Whereas violence is always an evil, it is sometimes a greater evil to run away from responsibility.)

According to Gandhi's ethics, explicitness is a duty. His politically relevant actions were innumerable, and he offered running commentary on them, factually as well as in terms of ethical appraisals. Few politicians have talked so much on the metalevel. Furthermore, because he never worked behind closed doors, there were always witnesses. We are spared the feeling

that the most important decisions, the most important statements of policy, were worked out in secret sessions.

The resulting vast material makes it practicable to work out broad interrelated groups of sentences representing rational reconstructions or models covering Gandhi's politically and ethically relevant behavior and attitudes.

The primary sources for this kind of reconstruction are historical documents and other materials concerning Gandhi's activities, his own systematic writings, his correspondence, and the conversations and speeches. They were recorded or summarized by D. G. Tendulkar, Shri Pyarelal, Mahadev Desai, and others. Much of this material has already been printed and is easily available.

If we were to mention a publication of particular value for rational reconstructions, I should choose the first volume of Gandhi's *Non-violence in Peace and War* (1942, 1944) edited by Desai, one of his distinguished companions. It includes not only a variety of newspaper articles and letters, but also recordings of conversations. They are all dated, and most of them refer to well-known political actions going on at the time. The concrete nature of the problems at issue does not reduce the philosophical value of the material. On the contrary, the interpretation of professional philosophers' ethical texts is usually hindered by an almost complete lack of reference to application in concrete situations. This is true of Plato, Hobbes, Nietzsche, and others. Without abundant application to concrete, historically well-known situations, ethical doctrines are impenetrable to analysis.

Of the many compilations of quotations from Gandhi, the enlarged edition of *The Mind of Mahatma Gandhi* (1967), edited by R. K. Prabhu and U. R. Rao, is outstanding. Unhappily, those extremely important sources from which we have already drawn, Gandhi's periodicals *Young India* and *Harijan*, are practically unavailable. References to these must therefore, in many cases, be supplemented by supporting references to the compilations.

In the following, one particular version, *E*, of one particular rational reconstruction of Gandhi's ethics is outlined in the form of a normative system. The system belongs to the class of systems that outline, structure, reflect, or portray not all Gandhian thought but primarily Gandhi's ethics of group struggle between 1907 and 1934. After 1934, political life in India becomes increasingly complicated, making it more difficult for Gandhi to apply his ideas in a simple, surveyable, unambiguous way.

Concerning the adequacy of Systematization *E*, the following should be added: The norms N_1 through N_{25} and most of the hypotheses are selected on the basis of a survey of norms and hypotheses in Gandhi's writings and the interpretation of his actions in campaigns. Some of our formulations are close to those of Gandhi; others are only indirectly or in part derived from him. Our main concern has been to ensure that all norms¹ of group ethics necessary to justify and explain *satyāgraha* (as described by Gandhi) are included in N_1 through N_{25} , and that no norm is contrary to the spirit of the formulations found in Gandhi's texts.² Thus completeness or comprehensiveness has ranked high in our choice of Systematization *E* among many different versions. Unhappily, the wideness of the perspective has necessitated a relatively high level of abstractness. For concrete applications that elucidate the abstract norms and hypotheses, one must consult the relevant sections in chapter 4.

The ethics of group struggle is conceived as a component of ethics in general, but with some degree of independence: the total set of its norms is derived from a very small number of norms, ultimately only one, which concerns group struggle in general. The dependence on general ethics is structurally shown by the derivation of a basic norm concerning group struggle from norms of other parts of ethics.

The dependence is also clear from the fact that some of the norms of the particular version of the ethics of group struggle outlined in what follows can be derived from norms of other parts of ethics by processes of inference that circumvent the basic norm of the ethics of group struggle. Thus, norm N_8 , "Do not humiliate or provoke your opponent," is derived from norm N_{14} and hypothesis H_9 , that is, from "If you are not able to subsume any of a group of relevant actions or attitudes as in themselves violent or constructive, then choose that action or attitude that most probably reduces the tendency to violence in the participants in the struggle" and "You invite violence from your opponent by humiliating and provoking him." However, norm N_8 might also be derived from a general code of conduct concerning behavior toward others, whether or not a struggle is imminent. The possibility of such circumventions is not, of course, very alarming. The historical data permit different explications of the relation between general ethics and the ethics of group struggle.

In what follows, we ignore directives as to how to fight for a bad cause—for instance, for an increase of violence—and assume tacitly that

the goal for a struggle is acceptable from the point of view of Gandhi's ethics as a whole. This assumption is used in relation to all hypotheses and norms of Systematization *E. The acceptance of the assumption is important because otherwise one cannot assume, as in H_2 , that there is an incompatibility between goal-directed motivation and destructive, violent tendencies. Destructive means are often good for destructive goals!

A systematization of Gandhi's ethics of group struggle with only one basic general norm appears to make all more specific norms instrumental and to rob all values, except those defined by the basic general norm, of their status as intrinsic values. Thus, if all more specific values are derived, then the only intrinsic good will be the realization of the basic general norm; all other values are instrumental. If all this is a fair interpretation of a pyramidal systematization, then we have arrived at a utilitarianism more comprehensive than that of, for instance, Fanon (see here on pp. 98 ff.), but a utilitarianism nevertheless.

This interpretation, however, is grossly misleading. "Universal self-realization" is not an object *in addition to* specific steps of self-realization at a definite time in a definite situation. The postulation or hypostatization of such an object would express a crude conceptual realism that is squarely incompatible with the function of systematizations. Further, the individual acts of seeking truth do not serve as instruments by which one creates something different from these acts, namely, "truth seeking in general." Thus individual steps toward self-realization and acts of truth seeking cannot without misapprehension be termed useful for universal self-realization and seeking of truth. The pyramid of norms and hypotheses is not one quality or value. The good attained by following a norm at the lowest level is not a good of the lowest kind, a slight and unimportant good. Levels of derivation do not correspond to levels of goodness or value or quality. Derivation depends on generality, not quality. A low value is not "derived" from a high value, a low norm is not derived from a high and more respectable norm.

Action is always specific and singular, therefore no norm can be followed if it is not specific enough to enlighten us about how to act in concrete situations. The lower levels of the pyramid are levels with increasingly specific norms and hypotheses. From "Act so as to minimize violence on this planet" nothing follows when one is in doubt about an act of sabo-

tage. A high place in the pyramid, taken in isolation, is on the whole an indication of lack of usefulness in practice.

Our conclusion: The relation of values defined by lower level norms to those defined by higher ones is not one of usefulness but one of derivation. Thus, this relation of values is not utilitarian in the sense of mere usefulness.

The Particular Norms and Hypotheses

A norm is said to be on level k , $k > 1$, if it is directly derived from a norm of level $k-1$. This is said to be so even if the derivation also requires acceptance of some hypotheses. A hypothesis is said to be of level k if it is used in the derivation of a norm of level k .

First and Second Levels

From “Act so as to reduce and eliminate violence,” $*N_3$ of the meta-physical systematization, we derive the level one or fundamental “norm of nonviolence in group struggle”:

$N_1 \equiv$ Act in group struggle and act, moreover, as an autonomous person in a way conducive to long-term, universal, maximal reduction of violence.

The derivation of N_1 from the basic general norms of self-realization and a hypothesis concerning the ultimateness of life permits us to picture the ethics of group struggle as an application of that norm to particular situations.

It should be noted that N_1 is not characteristic of consistent pacifist positions since it may, for instance, be argued without violating N_1 that killing in group struggle may be more conducive to the long-term, universal, maximal reduction of violence than not killing. We shall comment on the relation to pacifism later.

Sentence N_1 is intended to express the top norm of the system. All other norms are conceived to be derivable from this norm + hypotheses. The normative power of such pyramidal systems rests with N_1 and N_1 alone.

By there being only one top norm, dependence on the metaphysical position is reduced and made clear and simple. All derivations go through one checkpoint. On the other hand, some norms and hypotheses of Systematization *E* might, as we have already suggested, more naturally and comprehensively be derived from norms and hypotheses of the metaphysical position than from the exhortation to reduce violence in group struggle. The relative independence of the systematization from the details of a metaphysical view is, however, a decisive advantage, and it also makes it easier for others to substitute a different metaphysics from ours, retaining the basic norm of the group struggle system.

The *derivability* of all norms from a single norm does not imply that the top one has any higher normative status. Derivability is not of ethical import. Nor does the derivability of a norm mean that the realization of the norm does not represent a good in itself or an intrinsic value. "Make A. Smith happy" is derivable from "Make all Smiths happy," but this does not imply that it lacks intrinsic value to make A. Smith happy.

Instead of using the phrase "hypotheses and norms of the system," we could also employ the phrase "descriptions and prescriptions." The term *hypothesis* is used because it suggests what we wish to emphasize—the empirical, a posteriori character of the statements—and because we want by our terminology to constantly suggest the possibility and relevance of research programs revising norms and to reflect changes in political and social settings. Since all norms of the system except N_1 are prescribed under the condition that certain hypotheses are true, the whole system, except the single top norm N_1 , is, in principle, open to scrutiny from the point of view of empirical research. That is, the validity of every single statement of the ethics of group struggle depends on the truth and tenability of a set of empirical hypotheses. Gandhi looked on his life as one of *experimentation* with nonviolence.

It so happens that most of the hypotheses are at the moment to some extent testable by the techniques of the social sciences. Or, to be more modest: if the formulations of the hypotheses are made more precise by making use of the terminology dominant in social science today, we can find for each of our hypotheses at least one reformulation that expresses a scientifically testable working hypothesis.

The largely impersonal top norm N_1 is preferred to a norm that simply states, "Do not use violence" because, among other things, it would be too

narrow. The top norm envisages a reduction of violence in complete generality, not only the reduction of one's own violence. It is a pivotal point in Gandhi's thinking. Who does the violence? is a secondary question. Gandhi demands not only personal abstention from violence, but a conduct that does not provoke violence on the part of the opponent or anyone else affected by our conduct. Thus we should not humiliate an opponent by certain kinds of passive resistance because this is likely to produce hatred, which, in turn, may strengthen his disposition toward future use of violence. Further, Gandhi asks for a society, "the nonviolent society," that minimizes the potential role of violence.

There is another important aspect of N_1 : it requires that we *act* in group struggles. Seek the center of troubles and do not run away from the area of conflict. Here the basic attitude of the *karmayogin* reveals itself: one cannot retreat to the solitude of the Himalayas in order to better follow N_1 , because nonviolence by mere isolation from others is not likely to induce nonviolent behavior in others. It is by personal interaction in conflict situations that we can best reduce violence. Further, it is only in difficult (mostly also disagreeable) situations that we can hope to increase our own power of nonviolence. The "benevolent" bystander living in a peaceful suburb may turn out to be a beast when at last he is tested in a fierce riot, whereas a seasoned soldier may keep control of himself and apply nonviolence at a high level.

$H_1 \equiv$ The character of the means used in a group struggle determines the character of the results.

The means-end philosophy of Gandhi and of most other thinkers who feel at home in the camp of nonviolence is important not only from a theoretical point of view, but also didactically. In dialogues carried out in conflict situations, adherents to nonviolence show systematically less confidence in devious ways of arriving at goals generally accepted as good. However, in part because of its central character, the means-end philosophy does not lend itself easily to any clear single expression.

Gandhi sometimes formulated his view on this point in a paradoxical and categorical way. For instance, he says: "Means and ends are convertible terms in my philosophy of life. . . . They say, 'means are after all means.' I

would say, 'means are after all everything.' As the means so the end" (*Young India* 26.12.1924: 424 and 17.7.1924: 236–37; quoted in Prabhu and Rao 1967: 226). Taken verbally, the convertibility leads to paradoxes. If a strike is carried out in complete nonviolence, it does not ipso facto constitute the end. The strike is a means to an end, for instance, food for hungry workers. However ethically formidable in its implementation, a strike does not produce food. Nor does it make sense to invert the process, making food for hungry workers a means for achieving a strike.

There are, happily, other formulations that are more clear. Gandhi has expressed his idea in this way: "The means may be likened to a seed, the end to a tree; and there is just the same inviolable connection between the means and the end as there is between the seed and the tree" (*Hind Swaraj* 1958: 71; quoted in Prabhu and Rao 1967: 226). Taken literally, this formulation also leads to paradoxical or at least strange and awkward conclusions. We have tried to circumvent such interpretations by saying in H_1 that the character of the means determines the character of the results. This is very vague or indefinite, but it helps when combined with certain additions that introduce a typology of means and that also relate this typology to a typology of results.

When an action is said to be a means toward an end, no complete characterization is, of course, given of the action. The logic of these words is similar to that of "cause" and "effect."

Just as one and the same thing may be a cause in one relation and an effect in another, it may be a means in one and an end in another. There are chains of means and ends, just as in the case of causes and effects. (However, means do not *cause* the end.)

If, for example, what is designated by *means* is a definite raid and the end is political independence, there will nevertheless be a large number of actions that count as means in relation to that specific raid as their end. Think of preparations for the raid. Just as in the case of cause and effect, "means-end" is a relation that only takes care of the relata in respect to one single characteristic: the means-end relation.

This already precludes an adequate evaluation of an action that in a given case has a means-end relation to a given goal. Ends do not justify means, Gandhi asserts, just as motivation cannot justify actions—provided, of course, by *justify* we do mean something more than merely "contributing to a justification."

If a *satyāgraha* campaign is a campaign consistent with the ethics of nonviolence, any action that forms part of that campaign must be consistent with that ethics. That requirement already makes it clear that violence cannot be part of (100 percent) pure *satyāgraha*. Thus, if an action is a violent means to an end, no characterization of the end is needed in order to conclude that it cannot be part of (100 percent) pure *satyāgraha*. What is usually gained in ethics of nonviolence by postulating that “means determines ends” or even “means are exchangeable with ends” can be more convincingly and clearly gained by insisting, first, that any end or means in a conflict be subordinate to the norms of nonviolent struggle—it is not enough that ends be confronted with the norms—and, second, that ends definable as features of nonviolent society be anticipated by nonviolent means insofar as they involve acting as though in a nonviolent society. Use of a great variety of such means involves taking up the form of life envisaged for a nonviolent society. However, as long as the end, strictly speaking, includes the nonviolent behavior of the opponents, the (complete) end is not realized before the struggle ends in complete victory. Therefore, means and ends are not exchangeable or synonymous (convertible) if we compare behavior during the application of the means with behavior once the end (victory for nonviolence) has been achieved.

If we take self-realization to be the ultimate goal (as in Systematization *E) and a nonviolent society to be a necessary condition for reaching supremely high levels of self-realization, then all nonultimate ends and all means must be judged in relation to self-realization and the nonviolent society.

For some important means M_i advocated by Gandhi, “genuine, strong use of the means M_i ” and “realizing the end E_i , in relation to which M_i is a means” are very near each other, perhaps extensionally identical. This holds well for the means *ahimsā* in relation to “seeing God face to face” or “knowing God to the extent of seeing Him face to face.” Gandhi says that for him, the only certain means of knowing God is nonviolence—love. However, it is clear from other places that if a person performs perfectly pure *ahimsā*, he ipso facto “sees God face to face.” Perfectly pure *ahimsā*, however, must be considered practically impossible, at least for an individual in a violent society, because it implies complete self-realization and this can only be achieved when others have been dragged out of their violent habits. (“My self-realization is coupled to the self-realization of others.”)

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

$H_2 \equiv$ In a group struggle, you can keep the goal-directed motivation and the ability to work effectively for the realization of goals stronger than the destructive, violent tendencies and the tendencies to passiveness, despondency, or destruction only by making a constructive program part of your total campaign and by giving all phases of your struggle, as far as possible, a positive character.

By “struggle with a positive character” here is meant “struggle, some genuine parts of which show (concretely, perceptually) the desired end by partially anticipating it.” The struggle is, when positive, manifestly and evidently *for* something. Only by implication is the struggle against something. The constructive character is the manifest one; the destructive is implied. The violent opponent faces a state of affairs that shows him the desired end, not a group engaged in destruction or mere opposition against something not desired.

A quotation from Gandhi’s journal *Harijan* indicates how important he conceived the constructive program to be:

By hammering away at it through painful years, people have begun to see that there is a potency in non-violence, but they have not seen it in all its fulness and beauty. If they had responded to all the steps that had to be taken for the effective organization of non-violence and carried out in their fulness the various items of the eighteenfold constructive programme, our movement would have taken us to our goal. But today our minds are confused because our faith in constructive work is so weak. (*Harijan* 10.2.1946)

The goal alluded to in this quotation is “complete freedom (*pūrṇa svarāj*) for India,” that is, not only political independence from the British, but solution of the conflict between different religious communities (Hindus versus Muslims, Muslims versus Sikhs, etc.). The following quotation also illustrates the central position of the constructive programs:

Civil Disobedience, mass or individual, is an aid to constructive effort and is a full substitute for armed revolt. Training is necessary as well for civil disobedience as for armed revolt. Only the ways are different. Action in either case takes place only when occasion demands. Training for military revolt means learning the use of arms ending perhaps in the atomic bomb. For civil disobedience it means the Constructive Programme. (Gandhi 1945: 5)

$N_2 \equiv$ Make a constructive program part of your campaign.

N_2 is conceived as derivable from N_1 and H_2 . The special place of constructive programs in nonviolent struggles is further commented upon on pages 86 ff.

$H_3 \equiv$ Short-term violence counteracts long-term universal reduction of violence.

A violent man's activity is most visible, while it lasts. But it is always transitory . . . Hitler . . . Mussolini . . . and Stalin . . . are able to show the immediate effectiveness of violence. But it will be as transitory as that of Ghenghis' slaughter. But the effects of Buddha's non-violent action persist and are likely to grow with age. . . . [E]xperience convinces me that permanent good can never be the outcome of untruth and violence. Even if my belief is a fond delusion, it will be admitted that it is a fascinating delusion.

(Quoted in Pyarelal 1958, vol. 2: 802)

The qualification "long-term, universal" is used in order to provide a basis for the argument that, even if the short-term result of a war or a minor violent act may completely suppress a large-scale violence, the long-term effects of the use of violence result in more violence than was avoided as an immediate result.

I do not believe in armed risings. They are a remedy worse than the disease sought to be cured. They are a token of the spirit of revenge and impatience and anger. The method of violence cannot do good in the long run.

(*Young India* 9.6.1920: 3; quoted in Prabhu and Rao 1967: 139)

$N_3 \equiv$ Never resort to violence against your opponent.

Many people who favor war subscribe to N_1 . They conceive of war as a means to end all future wars or at least as a necessary evil on the way to ultimate reduction of violence. Norm N_3 goes against this and is conceived to be derivable from N_1 and H_3 .

Actually, no derivation is possible in any formal logical sense. Such derivation would require formalization of the system and the addition of a vast number of uninteresting premises that we have left out. Here we shall

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

only offer a point of departure for explications with highly explicit logical relations. Remarks similar to this are called for in many other instances in the following discussion where the terms *derive* and *derivable* are used. They are not used in the narrow sense of formal logic.

If a group *A* exploits *B* and a person or a group *C* starts *satyāgraha* on behalf of *B*, the aim of *satyāgraha* must be a state of affairs desirable for *A*, *B*, and *C*. The ideal of *satyāgraha* is to leave only victors when the struggle is over. Gandhi appealed to the British to leave India (as rulers) also for their own sake, and he meant it! Exploitation also “exploits” the exploiter: his self-realization is damaged, as not only Gandhi would affirm, but also theorists like Georg Hegel, Karl Marx, and Jean-Paul Sartre. Slaveowners are slaves of their slave ownership. In an area where Hindus dominate Muslims, domination hurts both, just as in areas of the opposite relation of domination. Exploitation is a form of violence (see *Harijan* 1.9.1940: 271–72; quoted in Prabhu and Rao 1967: 264–66), but it is a mutual violence, the exploiters against the exploited and the exploited against the exploiters.

In N_3 and in many norms and hypotheses that follow, we use such expressions as “the opponent,” “those for which we apply *satyāgraha*,” and so on. These refer to the manifest struggle. At a deeper level, *satyāgraha* is undertaken on behalf of all participants in the struggle. This point has been largely overlooked among theoreticians.

Satyāgraha is therefore, strictly speaking, done on behalf of the exploiters as well as the exploited. The manifest opponents are the exploiters, but the obstacles, the weaknesses that must be overcome, belong to both groups. The weaknesses foster the antagonism.

$N_{4a} \equiv$ Choose that action or attitude that most probably
reduces the tendency toward violence of all parties
in a struggle.

This norm is conceived to be derived from N_1 as a specification of it. It is an auxiliary norm we use when deriving N_{13} from H_{13} ; it stresses a nondiscriminating and comprehensive concern for all violence with which we might have contact. Outgroup violence is affected by our ingroup policies. Instead of N_3 , “Never resort to violence against your opponent,” we could have stated “Never resort to violence” or “Never do violence.” From $*N_1$,

“Seek complete self-realization,” and $*H_3$, “Violence against yourself precludes realizing your self,” follows “Do not resort to violence against yourself” (or we can derive this norm from $*N_1$ and $*H_5$). In giving N_3 the form we do, we are deliberately limiting ourselves to group struggle. In any case, the systematization admits a completely general norm against violence. Further, such a norm is not an instrumental norm; it is not utilitarian.

The systematization seems to present a utilitarian ethics of nonviolence because there is a supreme norm, “Seek complete self-realization,” above any norms against violence. However, this interpretation goes against the kind of derivation intended when deriving norms against violence from other norms, as explained on pages 57 f. The relation of nonviolence to self-realization is intrinsic (internal), not external. That is, a state of complete self-realization is intrinsically one of complete nonviolence. It is not like the relation between a strike and a resulting gain in foodstuffs for the workers. Analysis of the food cannot reveal the strike, in spite of the strike being used to achieve, and being instrumental in relation to, the improved state of nourishment. Analysis of a state of self-realization, however, reveals an absence of violence. Derivations in a normative system are not limited to external relations. On the contrary, the intrinsic relations are the normal ones. If this could not be taken for granted, the term *involvement explication* should be used instead of *derivation*. Self-realization involves nonviolence, according to Gandhi.

Nevertheless, Gandhi sometimes viewed nonviolence as of thoroughly instrumental value, or at least said things that might be thus interpreted, for example: “Nonviolence being a policy means that it can upon due notice be given up when it proves unsuccessful or ineffective” (Gandhi 1951b: 75).

$N_{4b} \equiv$ Never act as a mere functionary, a representative of an institution, or an underling, but always as an autonomous, fully responsible person.

The top norm, $*N_1$, “Seek complete self-realization,” involves realizing oneself as an autonomous, fully responsible person, and therefore also acting as such. Furthermore, $*N_2$, “Seek truth,” requires personal independence because truth is not a property or monopoly of any person or institution. Au-

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

tonomy as opposed to heteronomy does not involve more than personal identity: one's own, not someone else's, inner voice is the ultimate source of direction.

The next norms, twelve in all, are derived from norms N_2, N_3 , and N_{4a} with the aid of additional hypotheses, numbered H_4 through H_{17} . In order to facilitate the survey of the systematization as a whole, we shall proceed in a somewhat schematic way.

First-Level Norm:

N_1

Second-Level Norms and Hypotheses:

$H_1, H_2, H_3 \rightarrow$ the latter two derived from the former

$N_2 \rightarrow$ derived from N_1 and H_2

$N_3 \rightarrow$ derived from N_1 and H_3

$N_{4a} \rightarrow$ derived from N_1

$N_{4b} \rightarrow$ derived from N_1

Third-Level Hypotheses

We now proceed to the formulation of the third-level norms and hypotheses. As evidence of the Gandhian character of the latter, we shall sometimes interpolate one or more quotations from his writings, speeches, and dialogues. The weight of this evidence shows great variation from case to case. A more thorough documentation can be made by careful analysis of his campaigns.

The hypotheses of level 3 fall into four groups. The first have to do with securing constructivity and positivity (H_4, H_5, H_6, H_9); the second, with the securing of sympathetic understanding ($H_{10}, H_{11a}, H_{11b}, H_{12}, H_{13}, H_{16}$); the third, with the permanent possibility of convincing (H_{14}, H_{15}, H_{17}); and the fourth, with the role of common goals (H_7, H_8).

$H_4 \equiv$ You can give a struggle a constructive character only if you
conceive it and carry it through as a struggle in favor of human

beings and certain values, thus eventually fighting antagonisms, but not antagonists (positive struggle).

Antagonisms are defined structurally without specifying the function of particular persons. Where there are antagonisms, violence is already at hand as structural violence, or violence is to be expected.

$H_5 \equiv$ It increases your understanding of the conflict, of the participants, and of your own motivation to live together with the participants, especially with those for whom you primarily fight. The most adequate form for living together is that of engaging jointly in constructive work.

We use the qualification “primarily” in order not to create the misunderstanding that *satyāgraha* is carried out on behalf of only one of the contending groups.

$H_6 \equiv$ If you live together with those for whom you primarily struggle and do constructive work with them, this will create a natural basis for trust and confidence in you.

$H_7 \equiv$ All human beings have long-term interests in common (derivable from $*H_2$).

Development of the self toward maturity includes a process of widening interests and identifications. Therefore the self-realization of the mature self requires that of others. On the less metaphysical level, Gandhi stressed concrete, tangible common interests among groups in conflict. Hindus and Muslims, “touchables” and untouchables, landlords and peasants, capitalists and laborers.

I do not think there need be any clash between capital and labour. Each is dependent on the other.

(*Young India* 4.8.1927: 248; quoted in Prabhu and Rao 1967: 209)

The interdependence of conflict groups makes *satyāgraha*, not riots and police violence, the appropriate way of “fighting” it out. Such fighting may

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

result in the radical change of existing institutions. The interdependence does not imply that the group structure is permanent.

[I]f both labour and capital have the gift of intelligence equally developed in them and have confidence in their capacity to secure a fair deal, each at the hands of the other, they would get to respect and appreciate each other as equal partners in a common enterprise. They need not regard each other as inherently irreconcilable antagonists. (Prabhu and Rao 1967: 208)

$H_8 \equiv$ Cooperation on common goals reduces the chance that the actions and attitudes of participants in conflict will become violent.

$H_9 \equiv$ You invite violence from your opponent by humiliating or provoking him.

Thus, if as part of a boycott of a university or a shop, you lie down in the corridors so as to make it impossible for those seriously opposed to the boycott to avoid stepping on you, your opponent is humiliated. He may either refrain from entering the building for respectable ethical reasons or do it but with resentment and anger. He is not likely to be won to your case, but, on the contrary, he will be more willing to use and more able to justify extreme measures in the conflict, for instance, calling the police.

$H_{10} \equiv$ Thorough understanding of the relevant facts and factors increases the chance of a nonviolent realization of the goals of your campaign.

Gandhi devoted much of his time to acquiring a thorough knowledge of relevant circumstances before he acted. He warned his adherents against advocating their cause before they also deeply understood the different aspects of the problems involved.

$H_{11a} \equiv$ Incompleteness and distortion in your description of your case and the plans for your struggle reduce the chances both for a nonviolent realization of the goals and for the success of future struggles.

Rumor and loose talk played in India, just as they do in present-day conflicts, a fundamental role in fostering hatred of the antagonist or outgroup and complacency and righteousness in the ingroup. Organized violence depends on this incompleteness and distortion. "Truth is the first casualty in war," it is said; on the contrary its absence precedes war as a partial cause.

The classic kind of escalation can be seen in the following scenario: Muslim scolds Hindu boy who has stolen a cake; Hindus in next street tell about Hindu being beaten by Muslim; Hindu kicks Muslim, who denies the charge; Muslims in next street tell about the murder of a coreligionist; Muslims murder an innocent Hindu; . . . general riot.

$H_{11b} \equiv$ Secrecy reduces the chance of a nonviolent realization of the goals of your campaign.

The intention to keep certain plans, moves, motives, and objectives secret influences our behavior so that we cannot face our opponent openly (poker-face development). The intention and its implementation are also more easily revealed to the opponent than we are likely to believe. Our poker face alerts the opponent. Furthermore, once a secret is revealed, the opponent cannot know how many other secrets are kept, and a general suspicion poisons the communication channels.

On the other hand, if the opponent is in power, he may arrest all the leaders of a planned direct action. This stresses the need for democratic leadership, making it possible for a larger group to assume leadership.

The norm against secrecy is not a norm against refusal to give information that endangers the life of innocents.

$H_{12} \equiv$ You are less likely to take on a violent attitude if you make clearer to yourself the essential points in your cause and struggle.

A *satyāgraha* is not undertaken unless the fighters are convinced of the rightness of the cause. However, in an action, the direct confrontations are rarely with the most responsible opponents. More often, the direct confrontations are with subordinates of the opponents or with the police. In case of injury to material possessions, these possessions may belong to completely

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

innocent people. During direct actions, the distance between the positive aim of the campaign or movement and the concrete moves and doings of the fighters is considerable. Clear perception of both the positive aim and this distance makes it less likely that violence ensues: the nonviolent fighters are aware how misdirected, how *mal placé* the violence would be. They are aware of the futility of violence.

The importance, for Gandhi, of distinguishing essentials from nonessentials also derives from his teaching that one should always be willing to compromise on nonessential matters (cf. *N*₂₂, p. 82).

$H_{13} \equiv$ Your opponent is less likely to use violent means the better he understands your conduct and your case.

One might object that Hitler and many other leaders of group struggle profited immensely from ignorance. Knowledge of Hitler's conduct was apt to make his opponents consider any means! Against this we must respond with the reminder that the "case" must be consistent with the ethics of nonviolence—if not, Gandhi does not claim that anything will be gained from conducting the struggle nonviolently.

On the whole, Gandhi would insist that we inform our opponent more completely than is customary, even in rather friendly disputes, and that we do this by open actions rather than by proclamations.

$H_{14} \equiv$ There is a disposition in every opponent such that wholehearted, intelligent, strong, and persistent appeal in favor of a good cause is able to convince him ultimately (general convincibility).

In the application of the method of nonviolence, one must believe in the possibility of every person, however depraved, being reformed under humane and skilled treatment (*Harijan* 22.2.1942).

Gandhi tended to include any normal person in the intended field of validity of this hypothesis, interpreting "normal" widely enough to cover even Adolf Hitler. A person's capacity to convince the opponent may be inadequate, but it can be developed immensely.

Hitherto he [Hitler] and his likes have built upon their invariable experience that men yield to force. Unarmed men, women and children offering non-violent

resistance without any bitterness in them will be a novel experience for them. Who can dare say that it is not in their nature to respond to the higher and finer forces? They have the same soul that I have. . . .

(*Harijan* 15.10.1938: 290; quoted in Prabhu and Rao 1967: 149)

According to the metaphysics of Gandhi, all human beings, including Hitler, are ultimately one. It may be right, however, for a person to kill another. In the Third Reich, there were many situations of nonviolent helplessness in which Gandhi's norm to use violence rather than to surrender was applicable.

$H_{15} \equiv$ Mistrust stems from misjudgment, especially of the disposition of your opponent to answer trust with trust and mistrust with mistrust.

There are many examples in Gandhi's writings of this conception of trust and mistrust. His life likewise offers examples of the way he trusted people strongly opposed to him and the courage he thus proved. He repeatedly risked his own life by believing that he could trust his opponents when he met them personally. His "experiments" with trust were on the whole successful.

A grave question, however, is what to trust in the opponent. Sometimes one may press an opponent to promise something, but it would be quite unrealistic to expect him to keep the promise. Gandhi might say here that to trust a person does not mean to trust anything he says; it means to trust something in the opponent that listens to appeals and makes progress possible. The opposite, the mistrust of the whole person, is to give up any appeal.

$H_{16} \equiv$ The tendency to misjudge and misunderstand your opponent and his case in an unfavorable direction increases both his and your tendency to resort to violence.

When Gandhi arrived in Durban in 1897, people were enraged because of biased reports about his speeches in India concerning race discrimination in Durban and other places. He was severely attacked. Recovering, he gave a fair account of the incident, decreasing the chance of further violence. He was to experience similar verifications of his hypotheses during the next fifty years.

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

$H_{17} \equiv$ You win conclusively when you turn your opponent into a believer and active supporter of your case.

Persistent communication with the perceptible aim of convincing the opponent makes chances of solving the conflict greater than does communication that manifests resignation as to the possibility of influencing the beliefs of the opponent. If this sounds improbable, our reluctance to accept the hypothesis may stem from thinking in terms of pure conflicts of interest. Gandhian strategy presupposes common aims that bridge such conflicts. In matters of divergent interest (not touching upon justice), the strategy requires compromise.

No effort has been made explicitly to derive some of the hypotheses from others. By suitable modifications, H_{15} and H_{17} might, for instance, be derived from H_{14} .

Third-Level Norms

The third-level norms deal with the same four classes of subjects as the hypotheses that are used in their derivation—in short, principles of constructivity, understanding, convincing, and common goals.

$N_5 \equiv$ Fight antagonisms, not antagonists: conceive of your struggle and carry it through as a positive struggle in *favor* of human beings and certain values (derived from N_2 and H_4).

The essence of nonviolence technique is that it seeks to liquidate antagonisms but not the antagonists themselves. (*Harijan* 29.4.1939)

Nonviolence does not signify that man must not fight against the enemy, and by enemy is meant the evil which men do, not the human beings themselves.

My non-co-operation, though it is part of my creed, is a prelude to co-operation. My non-co-operation is with methods and systems, never with men.

(Prabhu and Rao 1967: 184)

It may be mentioned, as an example, that in the first part of his most famous campaign, Gandhi supported the people in making salt rather than instigating them to rise up against the empire salt producers and their fac-

tories. The desired situation was anticipated. One should fight the antagonism, not the antagonists.

$N_6 \equiv$ Live together with those for whom you struggle and do constructive work for them (derived from N_2 and H_5 or from N_4 and H_6).

Gandhi's experience in India covered hooliganism, riots, and many other kinds of violent disturbances. He did not have to deal with narcotics and gangs of rebellious youths. Studying the following quotations, the reader might have the typical social problems of the 1970s in mind. The main conclusion is that these problems can only be solved by large-scale mobilization of ordinary citizens, not by police action. The effort of the ordinary citizen to hire and pay a police army to solve problems he himself has created violates a number of Gandhian norms and hypotheses.

To quell riots non-violently, there must be true *ahimsā* in one's heart, and *ahimsā* that takes even the erring hooligan in its warm embrace. Such an attitude cannot be cultivated. It can only come as a prolonged and patient effort which must be made during peaceful times. The would-be member of a peace brigade should come into close touch and cultivate acquaintance with the so-called *goonda* (hooligan) element in his vicinity. He should know all and be known to all and win the hearts of all by his living and selfless service. No section should be regarded as too contemptible or mean to mix with. *Goondas* do not drop from the sky, nor do they spring from the earth like evil spirits. They are the product of social disorganization, and society therefore is responsible for their existence. (*Harijan* 15.9.1940; quoted in Gandhi 1944, vol. 1: 345)

They should contact the criminals in their homes, win their confidence and trust by loving and selfless service, wean them from evil and unclean habits and help to rehabilitate them by teaching them honest ways of living.
(Gandhi 1949a, vol. 2: 127)

I am a Hindu, I must fraternize with the Mussulmans and the rest. In my dealings with them I may not make any distinction between my coreligionists and those who might belong to a different faith. I would seek opportunities to serve them without any feeling of fear or unnaturalness. . . . Similarly, to meet the menace of thieves and dacoits, he will need to go among, and cultivate friendly relations with, the communities from which the thieves and dacoits generally come.
(*Harijan* 21.7.1940)

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

$N_7 \equiv$ Try to formulate the essential interests that you and your opponent have in common and try to establish a cooperation with your opponent on this basis (derived from N_2 and H_7 or from N_4 and H_7 and H_8).

Behind my non-co-operation there is always the keenest desire to co-operate on the slightest pretext even with the worst of opponents.

(Prabhu and Rao 1967: 183)

I would co-operate a thousand times with this Government to wean it from its career of crime, but I will not for a single moment cooperate with it to continue that career.

(Gandhi 1951b: 126)

$N_8 \equiv$ Do not humiliate or provoke your opponent (derived from N_3 or from N_4 and H_9).

When living and working together with opponents (and people on your own side), you provoke them if you try to impose your standards of conduct on them. "The golden rule of conduct," says Gandhi,

is mutual toleration, seeing that we will never all think alike and we shall always see Truth in fragment and from different angles of vision. Conscience is not the same thing for all. Whilst, therefore, it is a good guide for individual conduct, imposition of that conduct upon all will be an insufferable interference with everybody's freedom of conscience.

(*Young India* 23.9.1926: 334; quoted in Prabhu and Rao 1967: 420)

$N_9 \equiv$ Acquire the best possible understanding of the facts and factors relevant to the nonviolent realization of the goals of your cause (derived from N_4 and H_{10}).

In every branch of reform constant study giving one a mastery over one's subject is necessary. Ignorance is at the root of failures, partial or complete, of all reform movements whose merits are admitted. For every project masquerading under the name of reform is not necessarily worthy of being so designated.

(*Harijan* 24.4.1937; quoted in Bose 1948: 209)

$N_{10} \equiv$ Do your utmost to present unbiased descriptions, to be in full accordance with the truth when describing individuals, groups,

institutions, and circumstances relevant to the struggle
(derived from N_4 and H_{11a}).

In a fierce labor struggle, Gandhi attributed his success to the habit of correctness in details — factual truth:

Incorrect or misleading reports, therefore, . . . and their ire, instead of descending on me, would be sure to descend on the poor fear-stricken ryots and seriously hinder my search for the truth about the case.

In spite of these precautions the planters engineered against me a poisonous agitation. All sorts of falsehoods appeared in the press about my co-workers and myself. But my extreme cautiousness and my insistence on truth, even to the minutest detail, turned the edge of their sword.

(Gandhi 1948: 507)

On the other hand, there should be no soft-speaking when harsh truths must be communicated:

False notions of propriety or fear of wounding susceptibilities often deter people from saying what they mean and ultimately land them on shores of hypocrisy. But if non-violence of thought is to be evolved in individuals or societies or nations, truth has to be told, however harsh or unpopular it may appear to be for the moment. (*Harijan* 19.12.1936; quoted in Bose 1948: 151)

Of special importance is a close scrutiny of ingroup gossip. It is all too easy to form a pleasant but biased picture of the campaign when conversing with comrades. This is a main source of satisfactory relations between campaigners during inactivity. They tell each other nice things about the campaign that place the opponents in a ridiculous position. The ingroup feeling is supported by conformity and by falsity of the picture. However, interacting incorrectly with other groups and with the opponent may lead to false steps and undermine the success of the campaign. There are always warm, positive, nice things to be said that do not violate the norm of truthfulness.

$N_{11a} \equiv$ Do not use secret plans or moves or keep objectives secret
(derived from N_4 and H_{11b}).

No secret organization, however big, could do any good. Secrecy aims at building a wall of protection round you. *Ahimsā* disdains such protection. It

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

functions in the open and in the face of odds, the heaviest conceivable. We have to organize for action a vast people that have been crushed under the heel of unspeakable tyranny for centuries. They cannot be organized by any other than open truthful means. I have grown up from youth to 76 years in abhorrence of secrecy. (*Harijan* 10.2.1946; quoted in Gandhi 1949a, vol. 2: 2–3)

I do not appreciate any underground activity. I know that millions cannot go underground. Millions need not. A select few may fancy that they will bring swaraj to the millions by secretly directing their activity. Will this not be spoon-feeding? Only open challenge and open activity is for all to follow. Real Swaraj *must* be felt by all—man, woman and child. To labour for that consummation is true revolution.

(*Harijan* 3.3.1946; quoted in Gandhi 1949a, vol. 2: 50)

According to Gandhi, not all people have at all times the right to know everything about anything. Thus, it may be our duty to keep away information or plainly refuse to give certain information. Such cases were frequent during riots. Hooligans have no right to an answer when asking for the whereabouts of people they intend to rob or kill.

There is another aspect of the duty sometimes not to tell the truth. Gandhi formulated the principle “A reformer cannot be an informer.” Speaking at Uruli about a nonviolent attitude toward criminals, he stated that for a *satyāgrahin* to go to the police in order to give information “would be gross betrayal of trust.” He is also reported to have “mentioned several instances of how he had refused to give information to the police, about persons who had been guilty of violence and came and confessed to him. No police officer could compel a *satyāgrahin* to give evidence against a person who had confessed to him” (*Harijan* 11.8.1946; quoted in Gandhi 1949a, vol. 2: 126–27). A *satyāgrahin* would never be guilty of a betrayal of trust.

$N_{11b} \equiv$ Withdraw the intended victim from the wrongdoer (derived from N_4).

This norm has wide applications under terror regimes. It is often difficult to avoid a conflict of norms: the keeping away of potential victims from a criminalized police may develop into a large project requiring detailed planning that must be kept secret.

The wording of N_{11b} is taken from an article by Gandhi in his *Harijan* (part of it was quoted on page 43).

$N_{12} \equiv$ Announce your case and the goals of your campaign explicitly and clearly, distinguishing essentials from nonessentials (derived from N_4 and H_{12} and H_{13}).

$N_{13} \equiv$ Seek personal contact with your opponent and be available to him. Bring conflicting groups into personal contact (derived from N_4 and H_{13}).

The would-be member of a peace brigade should come into close touch and cultivate acquaintance with the so-called *goonda* (hooligan) element in his vicinity. He should know all and be known to all and win the hearts of all by his living and selfless service. No section should be regarded as too contemptible or mean to mix with. (Gandhi 1944, vol. 1: 344)

Peace brigades have a special mission in riot areas: . . . Theirs will be the duty of seeking occasions for bringing warring communities together, carrying on peace propaganda, engaging in activities that would bring and keep them in touch with every single person, male or female, adult or child, in their parish or division. (Gandhi 1944, vol. 1: 344)

Gandhi tried to come into personal contact with the British administrators and succeeded to an amazing degree. The graver the conflicts, the more intense was his effort to be in personal touch with the opponent.

Perhaps, however, Gandhi did not consistently make efforts to be in personal contact with the very shy and suspicious Jinnah, the Father of Pakistan. If that is the case, it was another mistake “of Himalayan dimensions,” judged from its consequences. It is difficult, however, to find the sources in studying the relation between Gandhi and Jinnah. One of its few students, S. K. Majumdar, has some painful things to point out:

Throughout 1937 and 1938, Jinnah tried his level best to come into personal contact with Gandhiji for the purpose of settling Congress-League disputes. But Gandhiji and the Congress High Command did not think it worth while to cultivate Jinnah’s good will. Feeling aggrieved . . . Jinnah became very bitter only when he found that his conciliatory overtures were contemptuously ignored. Until his self-respect was wounded, his speeches were never characterised by any bitterness, but . . . (Majumdar 1966: 159 and 160)

Some of the close collaborators of Gandhi in the 1940s say that it was impossible to penetrate Jinnah’s personal defenses. However, according to the hypotheses of *satyāgraha*, it must have been possible. Perhaps Gandhi did

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

not feel strong enough in his nonviolent attitude toward Jinnah? He talked surprisingly little about the possibilities of personal contact.

$N_{14} \equiv$ Do not judge your opponent harder than yourself (derived from N_3 or from N_4 and H_{16}).

$N_{15} \equiv$ Trust your opponent (derived from N_4 , H_{14} , H_{15} , and H_{16}).

A Satyāgrahi bids good-bye to fear. He is therefore never afraid of trusting the opponent. Even if the opponent plays him false twenty times, the Satyāgrahi is ready to trust him for the twenty-first time, for an implicit trust in human nature is the very essence of his creed. (Gandhi 1950: 246)

$N_{16} \equiv$ Turn your opponent into a believer in and supporter of your case, but do not coerce or exploit him (derived from N_1 , N_4 , H_{14} , and H_{17}).

The *satyāgrahi*'s object is to convert, not to coerce, the wrong-doer. (Prabhu and Rao 1967: 78)

But there is no such thing as compulsion in the scheme of non-violence. Reliance has to be placed upon ability to reach the intellect and the heart—the latter rather than the former. (*Harijan* 23.7.1938)

How can I, the champion of *ahimsā*, compel anyone to perform even a good act? Has not a well-known Englishman said that to make mistakes as a free man is better than being in bondage in order to avoid them? I believe in the truth of this. The reason is obvious. The mind of a man who remains good under compulsion cannot improve, in fact it worsens. And when compulsion is removed, all the defects well up to the surface with even greater force.—Moreover, no one should be a dictator.

(*Harijan* 29.9.1946; Gandhi 1949a, vol. 2: 138)

Despite much controversy about fasting as a coercive means, Gandhi persisted in the application of fasts. He considered them necessary companions of prayers.

My religion teaches me that, whenever there is distress which one cannot remove, one must fast and pray.

(*Young India* 25.9.1924: 319; quoted in Prabhu and Rao 1967: 34)

[T]here is no prayer without fasting, and there is no real fast without prayer.

(*Harijan* 16.2.1933: 2; quoted in Prabhu and Rao 1967: 35)

It is not to be denied that fasting can be really coercive. Such are fasts to attain a selfish object. . . . I would unhesitatingly advocate resistance of such undue influence. . . . (*Harijan* 9.9.1933: 5; quoted in Prabhu and Rao 1967: 36)

Coercion is taken to be a sort of violence and is therefore inconsistent with pure nonviolence. The questions of permissibility and avoidability of coercion have been debated. We shall discuss this issue separately.

Fourth-Level Hypotheses

A new set of hypotheses, together with norms N_8 , N_{10} , N_{14} , and N_{16} , will give rise to a last group of norms.

$H_{18} \equiv$ You provoke your opponent if you deliberately or carelessly destroy his property.

$H_{19} \equiv$ Adequate understanding of your opponent presupposes personal empathy.

Immediately we begin to think of things as our opponent thinks of them, we shall be able to do them full justice. I know that this requires a detached state of mind, and it is a state very difficult to reach. Nevertheless for a *satyāgrahi* it is absolutely essential. Three-fourths of the miseries and misunderstandings of the world will disappear, if we step into the shoes of our adversaries and understand their standpoint. (Bose 1948: 186)

$H_{20} \equiv$ Avoiding misjudging and misunderstanding your opponent and his case requires understanding him and his case.

$H_{21} \equiv$ If you keep in mind your own fallibility and failures, you are less likely to exaggerate those of your opponent. Opponents are then less likely to be misjudged in an unfavorable way, and their case is also less likely to be underestimated intellectually or morally.

$H_{22} \equiv$ Every political action, your own included, is likely to be based, in part, on mistaken views and to be carried out in an imperfect way (universal imperfection).

$H_{23} \equiv$ You make it difficult for your opponent to turn and support your case if you are unwilling to compromise on nonessentials.

$H_{24} \equiv$ It furthers the conversion of your opponent if he understands that you are sincere.

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

$H_{25} \equiv$ The best way of convincing your opponent of your sincerity is to make sacrifices for your cause.

The notion of sacrifice (and also suffering) in Gandhi's thought stems from the corresponding religious notion in the Baghavad Gita— consider the Sanskrit term *yajña* (“offer,” “token of devotion”). In nonviolent group struggle, hardships undertaken with joy for the cause count as sacrifice. “*Yajna* is not *yajna* if one feels it to be burdensome or annoying” (from Gandhi 1957; quoted in Prabhu and Rao 1967: 230).

The use of the terms *sacrifice* and *suffering* to translate *yajña* will suggest masochism to many Western readers. Let us therefore take note of Gandhi's explanation:

Yajna means an act directed to the welfare of others, done without desiring any return for it, whether of a temporal or spiritual nature. “Act” here must be taken in its widest sense, and includes thought and word, as well as deed. “Others” embraces not only humanity, but all life. . . .

(from Gandhi 1957; quoted in Prabhu and Rao 1967: 228)

The best way to convince the opponent is to make sacrifices for the cause, but hardships undertaken in order to impress the opponent are not *yajña*, according to the above quotation.

$H_{26} \equiv$ During a campaign, change of its declared objective makes it difficult for opponents to trust your sincerity.

Gandhi has in mind the expansion of objectives at moments of weakness in the opponent and contraction when it seems that the strength of the opponent has been underrated.

Fourth-Level Norms

$N_{17} \equiv$ Do not destroy property belonging to your opponent (derived from N_8 and H_{18}).

I see neither bravery nor sacrifice in destroying life or property for offence or defence. I would far rather leave, if I must, my crops and homestead for the enemy to use than destroy them for the sake of preventing their use by him. There is reason, sacrifice and even bravery in so leaving my homestead and

crops, if I do so not out of fear but because I refuse to regard anyone as my enemy — that is, out of a humanitarian motive. (Gandhi 1944, vol. 1: 388)

$N_{18} \equiv$ Cultivate personal *Einfühlung* (empathy) with your opponent
(derived from N_{14} and H_{19} and H_{20}).

By *Einfühlung*, we here think of placing oneself as much as possible in the situation of the opponent and understanding his actions in that context rather than one's own. It depends on the ability and willingness to identify with fellow humans, whatever their relation to one's own private interests. It does not, of course, preclude an intensive fight against the position of the opponent in the conflict. Gandhi's talk on the day after the unsuccessful attempt on his life (January 20, 1948), furnishes an example of how well he succeeded in his cultivation of personal *Einfühlung* with the opponent and of his consequent high level of unbiasedness. Tendulkar reports on this event:

God only knew how he would have behaved in front of a bomb aimed at him and exploding. Therefore, he deserved no praise. He would deserve a certificate only if he fell as a result of such an explosion, and yet retained a smile on his face and no malice against the doer. What he wanted to convey was that no one should look down upon the misguided young man who had thrown the bomb. [The youth] probably looked upon the speaker as an enemy of Hinduism. After all, had not the Gita said that whenever there was an evil-minded person damaging religion, God sent some one to put an end to his life? That celebrated verse had a special meaning. The youth should realize that those who differed from him were not necessarily evil. The evil had no life apart from the toleration of good people. (Tendulkar 1951–54, vol. 8: 331–32)

Gandhi knew that the people trying to take his life were devout Hindus. The one who succeeded (January 30) knew the Bhagavad Gita practically by heart, and the reference to the Bhagavad Gita in the above example must be said to make the opponent's view stand out in its full strength. That Gandhi was a kind of tyrant, that his followers were charmed and awed, not convinced by reason and sentiment, was a conviction held by a considerable minority. Among the leaders, Jinnah was of that opinion, and to one with a different philosophy of means and ends, it might easily be considered a virtue to get rid of Gandhi. The quotation ends with the metaphysical point that evil does not exist as such, but only insofar as it is tolerated by ordinary "good" people. This is a point taken up by many West-

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

ern philosophers, for example, Spinoza, and springs from the metaphysical conception of reality as something beyond good and evil.

$N_{19} \equiv$ Do not formulate your case, the goals of your campaign, or those of your opponent in a biased way (derived from N_{10} or from N_{14} and H_{20}).

$N_{20} \equiv$ Try to correct bias in your opponent only insofar as it is necessary for the campaign (derived from N_{10} or from N_{14} and H_{20}).

If your opponent describes your case in a biased way, this is not sufficient reason for you to use your time to try to correct him. If the misrepresentation is clearly relevant for the conduct and success of the campaign, an effort to change his presentation is advisable.

I am used to misrepresentation all my life. It is the lot of every public worker. He has to have a tough hide. Life would be burdensome if every misrepresentation had to be answered and cleared. It is a rule of life with me never to explain misrepresentations except when the cause requires correction. This rule has saved much time and worry. (Prabhu and Rao 1967: 7–8)

$N_{21} \equiv$ Keep in mind and admit your own factual and normative mistakes, and look for opportunities to correct your judgments (derived from N_{14} and H_{21}).

$N_{22} \equiv$ Always be willing to compromise on nonessentials (derived from N_{16} and H_{22} and H_{23}).

I am essentially a man of compromise, because I am never sure that I am right. (Fischer 1943: 102)

[F]ull surrender of non-essentials is a condition precedent to accession of internal strength to defend the essential by dying. (*Harijan* 10.11.1940: 333; quoted in Dhawan 1951: 129)

A Satyāgrahi never misses, can never miss, a chance of compromise on honourable terms, it being always assumed that, in the event of failure, he is ever ready to offer battle. He needs no previous preparation, his cards are always on the table. (Prabhu and Rao 1967: 172)

Indeed life is made of such compromises. *Abimsā* simply because it is purest, unselfish love, often demands such compromises. The conditions are impera-

tive. There should be no self in one's action, no fear, no untruth, and it must be in furtherance of the cause of *ahimsā*. The compromise must be natural to one-self, not imposed from without. (Gandhi 1944, vol. 1: 126–27)

All my life through, the very insistence on truth has taught me to appreciate the beauty of compromise. I saw in later life, that this was an essential part of *satyāgraha*. It has often meant endangering my life and incurring the displeasure of friends. But truth is hard as adamant and tender as a blossom.

Human life is a series of compromises, and it is not always easy to achieve in practice what one has found to be true in theory.

There are eternal principles which admit of no compromise, and one must be prepared to lay down one's life in the practice of them.

(Prabhu and Rao 1967: 39)

$N_{23} \equiv$ Do not exploit a weakness in the position of your opponent
(derived from N_{16} and H_{24}).

This highly characteristic norm is commented on below (pp. 87 f.).

$N_{24} \equiv$ Be willing to make sacrifices and suffer for your cause (derived
from N_{16} and H_{24} and H_{25}).

In passive resistance there is always present an idea of harassing the other party and there is a simultaneous readiness to undergo any hardships entailed upon us by such activity; while in *satyāgraha* there is not the remotest idea of injuring the opponent. *Satyāgraha* postulates the conquest of the adversary by suffering in one's own person. (Bose 1948: 185)

Self-sacrifice of one innocent man is a million times more potent than the sacrifice of a million men who die in the act of killing others. The willing sacrifice of the innocent is the most powerful retort to insolent tyranny that has yet been conceived by God or man.

(*Young India* 12.2.1925: 60; quoted in Prabhu and Rao 1967: 139)

Gandhi has made it clear that the suffering, that is, the hardship, must be functional. He was not in favor of martyrs or sufferings not caused by acts conducive to the solution of the present conflict or future potential conflicts.

$N_{25} \equiv$ During a campaign, do not change its objective by making its
goals wider or narrower (derived from N_{16} and H_{24} and H_{26}).

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

In a pure fight the fighters would never go beyond the objective fixed when the fight began even if they received an accession to their strength in the course of the fighting, and on the other hand they could not give up their objective if they found their strength dwindling away.

(Gandhi 1950: 422–23)

I distinctly said, that it would be dishonest now, having the opportunity, to take up a position which was not in view when *Satyāgraha* was started. No matter how strong we were, the present struggle must close when the demands for which it was commenced were accepted. I am confident, that if we had not adhered to this principle, instead of winning, we would not only have lost all along the line, but also forfeited the sympathy which had been enlisted in our favour. On the other hand if the adversary himself creates new difficulties for us while the struggle is in progress, they become automatically included in it. A Satyāgrahi without being false to his faith, cannot disregard new difficulties which confront him while he is pursuing his own course.

(Ibid., pp. 209–10)

For the proper use of this norm, we shall distinguish between action, campaign, and movement: Gandhi planned and carried out a number of campaigns for political independence of India and also a number of campaigns for other large goals, for example, the abolition of untouchability and mutual tolerance and respect between religious communities. The always well defined and limited campaigns are thus parts of larger, sometimes more ill defined, diffuse movements with supreme goals. The latter are in general not liable to precise delimitation. *Svarāj* was never defined or specified, leaving each group some freedom of interpretation. “Communal peace” was even less definite. Norms pertaining to campaigns are therefore not automatically generalized to movements. If the two are not kept apart, we are apt to require too much of movements and too little of campaigns. Within campaigns, we may speak of direct actions. Thus, the salt march might be taken as one action and the salt raids as other actions within the “abolish the salt monopoly” campaign. This example, however, is a difficult one, as it appears to suggest that the borderline between action, campaigns, and movement cannot be defined precisely.

Norm N_{25} says essentially that the opponent must get an honest answer to “What do you want through your present action?” and that if we achieve what we have said we want, then that action is to be terminated, whether its termination is opportune or not.

Elaboration and Exemplification

Constructive Programs

In this section, we shall illustrate how the above meager outline of a systematization can be taken as a starting point for a more substantial presentation. First, we shall elaborate on one of the norms of the system, N_2 , “Make a constructive program part of your campaign,” in order to make it more understandable and also more open to critical examination. The paramount importance of this norm stems in part from Gandhi’s conviction that if it is ignored by some sections of the supporters of *satyāgraha*, the strongest non-violent methods in the fight for political freedom are rendered inapplicable. Only those who are able to take upon themselves the task of constructive community service are sufficiently mature for intense massive nonviolent struggle. At a critical juncture in 1930, Gandhi stressed that he could not recommend civil disobedience campaigns because the requirement of a constructive program was unlikely to be fulfilled. Insufficient constructive content in the fight for freedom would make it overwhelmingly probable that there would be violence and that the people, even if victorious, would prove to be too immature for implementing radical reforms.

Gandhi was determined to stop a civil disobedience campaign in the case of such immaturity, as at Chaura Chauri, where some English policemen were murdered. However, only late in his life was he able to admit to himself how far behind he was in developing an institution of constructive work.

Gandhi insisted on constructive or positive conceptions of goals and subgoals and consequently demanded that Indians belonging to groups likely to get into violent conflict in case of crisis should work together on economic and other projects, thereby acquiring a spirit of mutual understanding and trust and a habit of sacrifice, that is, of engagement in the interest of wider long-range goals.

In India, such work was organized and planned under the name of the Constructive Program. The norms stating that one should contribute to the implementation of the constructive program make up an integral part of the Gandhian ethics of group struggle. They are not mere accessories.

A quotation will make the point clearer. In his statement of January 1930, Gandhi said among other things that the atmosphere was not conducive for initiating a mass civil disobedience campaign:

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

Constructive programme is not essential for local civil disobedience for specific relief as in the case of Bardoli. Tangible common grievance restricted to a particular locality is enough. But for such an indefinable thing as Swaraj (freedom), people must have previous training in doing things of All-India interest. Trust begotten in the pursuit of continuous constructive work becomes a tremendous asset at the critical moment. Constructive work therefore is for a non-violent army what drilling etc., is for an army designed for bloody warfare. Individual civil disobedience among an unprepared people and by leaders not known to or trusted by them is of no avail, a mass civil disobedience is an impossibility. The more therefore the progress of the constructive programme, the greater is the chance for civil disobedience. Granted a perfectly non-violent atmosphere and a fulfilled constructive programme, I would undertake to lead a mass civil disobedience struggle to a successful issue in the space of a few months.

(*Young India* 9.1.1930)

In the booklet *Constructive Programme*, Gandhi even says that mass civil disobedience might be dispensed with if the constructive program were taken seriously by all concerned. He says:

Civil disobedience is not absolutely necessary to win freedom through purely non-violent efforts, if the cooperation of the whole nation is secured in the constructive programme. . . . My handling of civil disobedience without constructive programme will be like a paralysed hand attempting to lift a spoon.

(Diwakar 1946: 187)

Constructive work, on the other hand, cannot be dispensed with:

The best preparation for, and even the expression of, non-violence lies in the determined pursuit of the constructive programme. Any one who believes that without the backing of the constructive programme he will show non-violent strength when the testing time comes will fail miserably. It will be, like the attempt of a starving unarmed man to match his physical strength against a fully fed and panoplied soldier, foredoomed to failure.

(Gandhi 1944, vol. 1: 398–99)

The constructive work is of various kinds. A few of the many activities one might work to promote include eliminating untouchability, spreading hand-spun and handwoven cloth, developing village sanitation and other village industries, cultivating basic education through crafts, and creating literacy programs.

Gandhi also had in mind the effect on the opponent. In the eyes of the opponent, the revolutionary seems mainly to have destruction in view.

Gandhi requires methods whereby the constructive intent is made completely clear and trustworthy to the sceptical opponent.

As a demonstration against the British salt tax and salt monopoly, considered to be profoundly unjust, Gandhi and a mass of poor people marched to the sea to make salt illegally. While the campaign was going on, Gandhi used much time for other tasks, such as instigating house industry and cleaning up slum quarters. The latter activity was a genuine part of the campaign and part of the struggle for *svarāj* as a whole. It was a demonstration *ad oculos* that helped the followers and opponents fix their attention on the positive goals rather than on the means and the inevitable destructive components, that is, disabling the British administration.

One may say that the norm to partake in a constructive program is the supreme anti-antimovement norm in the system: those tendencies present in organizations or groups that favor the destruction of something (the organized anti-Semites, anti-Communists, anti-Fascists, etc.) are denounced; every action should have a clear, positive pro-character.

We have used the norm “Give your campaign a constructive content” to illustrate the rich, scarcely surveyable material that has to be studied in order to proceed from a mere diagram toward a full presentation of Gandhi’s political ethics. It should be clear from the comments and quotations that constructivity of main goals, constructivity of subgoals, and the so-called constructive program are means by which Gandhi tried to contribute to the implementation of many norms. It should also be clear that some norms may be viewed as occupying a lower position in relation to the norm requiring constructive work. Actually, the constructive work was a kind of partial anticipation of the condition Gandhi called *pūrṇa svarāj*, real independence, an ideal state of society. The political independence was not, as such, a constructive goal for him, since it was defined as *absence* of British domination.

Nonexploitation of Weakness

Let us elaborate on another norm, N_{23} , “Do not exploit a weakness in the position of your opponent,” that is, insofar as the weakness is due to factors irrelevant to the struggle.

Victory in the sense of bringing the opponent to accept the stipulated conditions for terminating the *satyāgraha* is not necessarily a victory of the kind intended by the *satyāgrahin*. If the surrender is caused by some misfor-

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

tune the opponent has experienced that makes it necessary for him to call off his struggle with the *satyāgrahin*, the opponent may, after the surrender, be as much opposed to the goal of the *satyāgraha* as before it all started. Surrender without conversion is not the ideal kind of termination of the struggle. If by factors irrelevant to the struggle and therefore unrelated to the conversion of the opponent, the *satyāgrahin* are able to get what they desire in terms of conditions, they should, if it is practicable, postpone the campaign until the opponent has recovered his full strength.

As an example, we may take what happened at the last stage of the *satyāgraha* campaigns in South Africa. Gandhi fought against certain laws that he considered discriminatory against the Indian minority. Their repeal was the condition of bringing the *satyāgraha* campaign to a stop. The Indian leaders were planning a march as part of the *satyāgraha*. When a railway strike broke out among the white employees, the government was in a dangerous position and might well have been willing to settle the conflict with the Indians in order to meet the situation created by the strike. Let me quote what Gandhi says in his narrative. Its reliability is not contested by his adversary — and great admirer — General Smuts. Gandhi said:

Just at this time there was a great strike of the European employees of the Union railways, which made the position of the Government extremely delicate. I was called upon to commence the Indian march at such a fortunate juncture. But I declared that the Indians could not thus assist the railway strikers, as they [the Indians] were not out to harass the Government, their struggle being entirely different and differently conceived. Even if we undertook the march, we would begin it at some other time when the railway trouble had ended. This decision of ours created a deep impression, and was cabled to England by Reuter. (Gandhi 1950: 325)

When World War II broke out, pressure was brought on Gandhi to intensify the fight against the British. He declined to take up mass civil disobedience during the war. He said:

There is neither warrant nor atmosphere for mass action. That would be naked embarrassment and a betrayal of nonviolence. . . . By causing embarrassment at this stage, the authorities must resent it bitterly, and are likely to act madly. It is worse than suicide to resort to violence that is embarrassment under the cover of nonviolence.

(Declaration published in all Indian newspapers, October 30, 1940)

Gandhi's argumentation and behavior in these two instances are in conformity with his admonition to not exploit weaknesses in our opponents' position (N_{23}).

Later, during World War II, Gandhi intended to start a mass movement. This plan creates a problem for our Systematization *E*. It requires either a hypothesis that the British then, in the autumn of 1942, were no longer in a temporarily weak position, or a decision that Gandhi violated his own norms, or perhaps a decision to modify our systematization so as to make Gandhi's behavior in both 1920 and 1942 conform to the explication of his ethics. We tentatively take the view that in 1942 Gandhi violated his own norms and are thus able to continue to regard the metaphysical Systematization $*E$ as adequate.

Coercion

Inherent in the concept of group struggle is an acknowledgment of a conflict of wills. "I do not want what you want, and I oppose you." When a *satyāgraha* campaign starts, a conflict of wills is taken for granted.

By definition, a successful *satyāgraha* campaign ends with wills in harmony (within the field covered by the always limited campaign). Normally, the direction of the wills of both parties is changed during the campaign. The antagonism disappears within a limited area without anyone being the victor. There is no vanquished and, therefore, no victor, but there is a victory. How this has happened is demonstrated in the history of *satyāgraha* campaigns; it is not our topic here.

If the parties had heard beforehand about the solution to be agreed on afterward, they would normally have rejected it as contrary to their will. Conceptually, this does not imply that the *satyāgraha* campaign forced a solution on the unwilling contestants. Coercion is not conceptually implied.

This conceptual discussion of volition and *satyāgraha* is important for its clarifying power in relation to the unfortunate acceptance by some researchers of coercion as a positive ingredient in a *satyāgraha* campaign. Thus, Joan Bondurant argues:

Coercion has been defined as "the use of either physical or intangible force to compel action contrary to the will or reasoned judgment of the individual or group subjected to such force." Despite the protestations of a few followers of

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

Gandhi that satyāgraha is always persuasive and never coercive the method does contain a positive element of coercion. Non-cooperation, boycott, strike—all of these tools which may be used in satyāgraha involve an element of compulsion which may effect a change on the part of an opponent which initially was contrary to his will—and he may suffer from the indirect results of these actions. (Bondurant 1958: 9)

As a consequence of her stand at this point, Bondurant also thinks that ideal democracy, the non-coercive society as conceived by Gandhi, retains and therefore contains an element of coercion. “Dhawan errs,” Bondurant contends, when he suggests that Gandhi’s democracy would be “based on non-violence instead of coercion” (ibid., p. 173). As statements of principle not concerned with more or less unavoidable weaknesses in practice, these contentions are important.

Let us, for the sake of discussion, retain the definition of *coercion* by Paullin, adding the version suggested by Bondurant, “application of either physical or moral force to induce another to do something against his will” (ibid., p. 10; for the above-mentioned definition of *coercion* see Paullin 1944: 6).

Suppose person *P* wills *A* at time t_1 and *B* at time t_2 . Something has changed the direction of *P*’s will, and this could not have been his will itself (he neither willed to nor willed not to change his will!), but something foreign to his will. However, from this influence of something on the direction of *P*’s will, one cannot infer that *P* was coerced. Any change of opinion, for instance, may influence the direction. That *P* at time t_1 would have rejected a settlement *B* of a conflict that at time t_2 he accepted is not an indication that he was coerced into willing *B*. He may not have been coerced at all by any person in any respect during the interval t_2-t_1 . If he were *led* to acquire certain information or to receive certain impressions (perceptions) of suffering and these changed his reasoned judgment, we would not say he was coerced.

If the change of will follows a scrutiny of norms and hypotheses in a state of full mental and bodily powers, this is an act within the realm of personal freedom. *P* exercises his freedom of will—he changes his opinion under optimal conditions. The closing of ears and eyes and maximal obstinacy is not characteristic of a person with reasoned judgment. If a pure *satyāgraha* was required to end with a settlement that had already been agreeable to both parties at the beginning of the conflict, why ever start a

satyāgraha? Normally the ultimate formula agreed on after a *satyāgraha* campaign would not be agreeable—or even understandable—to the opponents before the *satyāgraha* was started.

Suppose, for a moment, that *M* carries *P* against his will into the streets where there is a riot and that as a consequence of what he sees, *P* changes some of his attitudes and opinions. Was the change coerced? We suggest that the change of *P*'s opinions or attitudes was not coerced, but that *P* himself was coerced into seeing something that caused the change. The distinction is relevant because *satyāgraha* is certainly incompatible with coerced changes of opinions or attitudes. Gandhi himself insisted on convincing, not coercing. "Coercion is inhuman" (*Harijan* 24.3.1946; Gandhi 1960: 238).

Even if changes of opinion or attitude are uncoerced, a *satyāgraha* may involve coercion: opponents may perhaps be forced or compelled to witness certain things or to hear certain arguments. However, coercion within a campaign decreases the degree of its consistency. It is characteristic that this anticoercive view of *satyāgraha* colors the excellent exposition by Bondurant in spite of her theoretical acceptance of coercion as a genuine element of *satyāgraha*:

In the instance of the Ahmedabad *satyāgraha*, Gandhi came to see that his fasting introduced an element of coercion which detracted from the true character of *satyāgraha*. The adherence to persuasion as opposed to coercion was best exemplified in the Vykom *satyāgraha*: after the State had withdrawn its support of the opposition and the roads had been legally opened to untouchables, the *satyāgrahis* did not take advantage of this development to enter the roads against the persisting opposition of the Brahmans. They continued the *satyāgraha* until they had persuaded their opponents that denial of passage to untouchables was morally indefensible. . . . In examining *satyāgraha* in action, it becomes clear that *satyāgraha* operates as a force to effect change.

(Bondurant 1958: 104)

Satyāgraha operates as a force to affect change—a keen force to affect deep changes. However, a force does not have to *force*. This makes *satyāgraha* possible. Where there is an element of forcing, of coercion, it is Gandhi's claim that the *satyāgrahin* by his or her training and outlook should be able to detect and get rid of it. He himself did not always succeed. Thus, in the fight against the position of certain mill owners, some of whom were his friends and therefore concerned about his health, Gandhi nevertheless initiated a fast:

NORMS AND HYPOTHESES OF GANDHIAN ETHICS

With the mill-owners, I could only plead; to fast against them would amount to coercion. Yet in spite of my knowledge that my fast was bound to put pressure upon them, as in fact it did, I felt I could not help it. The duty to undertake it seemed to me to be clear. (Gandhi 1948: 528)

The fast had other aims than to *make* the mill owners change their position. However, the negative side effect, the pressure put on these people, Gandhi thought he had to put into the bargain. The result was a *satyāgraha* of less than 100 percent purity, but this outcome does not undermine the position that *satyāgraha* may be carried through without such pressures.

If the above is acceptable, Dhawan's short characterization of Gandhi's conception of the ideal democracy may be adequate: a classless society "of autonomous village communities based on nonviolence instead of coercion, on service instead of exploitation, on renunciation instead of acquisitiveness and on the largest measure of local and individual initiative instead of centralization" (Dhawan 1946: 3).

Strict and Less Strict *Satyāgraha*

The foregoing system of norms formidably restricts the field of justifiable forms of conflict resolution. It is, however, the claim of the proponents of ethics of nonviolence that such a system omits no form of conflict resolution that is effective in the long run. It is presupposed that the goal is justifiable from the point of view of general ethics. It is claimed, therefore, that no effective (powerful, adequate) form is excluded for those who fight for an ethically acceptable cause.

The criteria of goodness offered by Gandhi and others are such that no statesmen today would openly reject them. That is, contemporary men in power would proclaim their goals to be good in the sense required. They claim justice, legitimate interest, and freedom as goals. (Whether their practice supports the claims is another question.)

Defining a maximally strict *satyāgraha* campaign as a group struggle completely fulfilling the norms of nonviolent group struggle (here represented by Systematization *E), we have an ideal that one cannot expect to be realized anywhere. However serious the intention of the leaders to realize the ideal struggle, one may expect that the situation sometimes at least momentarily gets out of control or that slight violations of at least one norm

simply “happen” in the heat of the struggle. Then there are circumstances under which even leaders with advanced nonviolent attitudes will deliberately violate one or more norms.

Let hundreds like me perish, but let truth prevail. Let us not reduce the standard of truth even by a hair's breadth for judging erring mortals like myself.
(Gandhi 1948: 7)

Gandhi stressed the importance of holding up an ideal of *ahimsā* even if we do not “practice that doctrine in its entirety” (see the quotation on page 44). The standards of nonviolence should not be lowered: “It would be wholly wrong for us to lower the standards of ahimsa because of our own frailty or lack of experience. Without true understanding of the ideal, we can never hope to reach it” (*Harijan* 28.4.1946). One might add that without adequate understanding of the maximum requirements or the ideal requirements, there will be inadequate understanding of the lesser requirements and the approximations.

A typology of violations must work with several dimensions: with the number of violations of each norm and the seriousness of the violence; with intentionality, i.e., the question of whether the leaders “should have foreseen the eventuality of this or that violation (at certain stages) and made precautionary measures” or their “degree of recklessness in hoping for the best”; and with the extent to which violations are due to non-belief in certain hypotheses.

Thus, we may believe in exceptions to H_{18} , “You provoke your opponent if you deliberately or carelessly destroy his property.” Destruction of instruments of mishandling or of weapons might in some cases be understood by the immediate opponent. Tiny pieces of technical installation could be destroyed in order to avoid great destruction of nature (dams).

More importantly, one might replace the term *violence* in N_1 (“Act in group struggle and act, moreover, as an autonomous person in a way conducive to long-term, universal, maximal reduction of violence”) with *injury*, and claim that the opponent is not always injured by physical violence. A man educated in the tradition of the Wild West may understand a left to the jaw much better than other forms of being shaken up. In riots, the use of fists against looters may have a good effect, some might maintain. In addition, many would claim that nonviolence left them altogether

helpless in the case of the rapid development of a riot or of some other great physical disturbance. Thus, very few would in practice believe in the empirical basis of N_3 , "Never to resort to violence against your opponent."

The multitude of forms of non-quite-strict *satyāgraha* campaigns make them unsuitable for systematic formulation. This is the basis for our strongest counterargument against those who think that the systematization of an absolutely strict *satyāgraha* is unimportant because of the unlikelihood of there being any case of its realization. It is considered too idealistic, remote, and moralizing. However, if we ask these "realists," What systematization do you favor, if any? there is such a diversity of answers, so much arbitrariness in the rules adapted to a reasonably realistic code, as to frustrate all efforts at systematization.

For example, the realist says that some sort of secrecy must sometimes be used. Yes, but how are we to make rules about it? Where are we to draw the line between justifiable and unjustifiable secrecy within *satyāgraha*? The outcome of attempts to formulate rules tends to show that it is better to keep the formulations of the ideal *satyāgraha*, banning secrecy without qualifications, but to introduce somewhat narrow criteria of secrecy, making it different from merely not answering a question or not publishing a plan for direct action.

Take as an instance the important rule of nonviolence that says there is some piece of information that it is your duty to withhold. It cannot be your duty "to tell the truth" about the place where your children are hiding during a riot. The negation of " x tells the truth to y " is not " x tells something untrue to y ," but "it is not so that x tells the truth to y ." There is room for every thinkable behavior except one: *telling* the truth. Within that room, you have, for instance, the option of silence. However, in what cases does silence in such a context constitute dishonesty, untruthfulness, and therefore *himsā*? It seems clear that the protection of innocents against a wild mob, an execution unit of the SS, or any other group or individual set on murder more or less inevitably leads to infringements of some codes of nonviolence and that ethical assessment of the relative seriousness of the violations cannot be made on the basis of a systematization of nonviolence, if on the basis of systematization at all.

We are not, of course, arguing here that systematizations can solve a problem of ethical decision. In the last analysis, the acting person has to reaffirm his adherence to a rule before applying it, and this reaffirmation

does not have its sole justification in any rule. Otherwise, the individual retreats from his status as an individual person. There is no automatism in ethics! We may derive norms from other norms, but not ethically relevant decisions.

Mostly the argumentation against the systematization of pure nonviolent struggle is based on an absolutistic, methodologically naive conception of the aim of a systematization. Only close discussion of scientific methodology can help here. One must make oneself familiar with the peculiar aspect of the use of models and reconstructions, in short, with the *heuristics* of theory construction.

We know from physics, economics, and other sciences that concepts and theories may not fit anywhere but may nevertheless be fruitful. Thus, although the concepts of a vacuum, rigid bodies, economic man, free enterprise, and so forth, do not strictly apply anywhere, they have been useful as part of the scientific enterprise. However, that *part* must not be located incorrectly!

A thorough discussion of the role of systematization tends to conclude with agreement on a rather modest conception of systematization. Our adversary may then exclaim: "Is that all you are trying to do! How can you spend months or even years of your life on such modest aims?" This is a very understandable reaction, but a subsequent question put to the adversary about what *he* deems more rewarding tends to confirm the systematizer in his belief that he hasn't done so badly in his choice of occupation.

IV

Nonviolence and the “New Violence”

The Contemporary Reaction Against Nonviolence

The period spanning the mid-1960s to the mid-1970s witnessed an upsurge of physical violence and a proliferation of recommendations to use manifest violence, physical and verbal. It inundated colonial, racial, and educational controversies in Europe, America, India, and many other areas. Sometimes it has been systematically and consistently anti-Gandhian, being in part a direct reaction against the limited success of Gandhian and pseudo-Gandhian preaching and practice.

We shall not enter here into the controversies about the causes of this development, which we vaguely characterize as the “new violence.” A symptom, rather than a cause, is widespread dissatisfaction, indignation, and impatience when considering the slowness of the movement of liberation in the colonial, racial, and educational spheres. The imperatives “Do it quicker!” and “Freedom *now!*” have testified to this demand for immediate, radical change. The slogan “Revolution!” has invaded all spheres of discussion. Revolution is generally conceived as a violent overthrowing, idealizing “power over” and coercion at the cost of “power to.” Changes should be forced on opponents; agreement and compromise should be shunned. The slogans are sometimes formed consciously so as to be in direct opposition to the preaching of nonviolence.

Young leaders of opinion mostly have no knowledge of the revolutionary aspects of Gandhi’s campaigns. This even seems to hold for Indian leaders. Their image of him is more likely to be of a man concerned with means rather than with ends, more concerned with prevention of open violence than with the elimination of the hidden structural violence built into societies in the form of exploitation. They do not know that Gandhi intended

NONVIOLENCE AND THE “NEW VIOLENCE”

to make, and in fact made, gigantic efforts to destroy structural violence and that his timetable was that of a revolutionary. This fact is important for assessing the potential that improved information on Gandhi might have in the future—even if it must be admitted that Gandhi did not achieve the rapid changes he envisaged early in his life.

Young people on several continents have joined the reaction against the preaching of consistent nonviolence. It is in many ways a fight against the vast flood of hypocrisy, false idealism, suppressed hatreds, and disguised sadism that masquerade as civility, peacefulness, and tolerance. It is perhaps also part of youth’s painful realization of lack of spontaneity and genuine self-expression. The usual descriptions of Gandhian ideology stress moralism, saintliness, humility, and sacrifice (conventionally interpreted) and neglect the basic norm that you should follow your inner voice whatever the consequences. The distortion has contributed to the neglect of militant nonviolence as a possible way of protest.

The new emphasis on violence is clearly formulated by such leaders and authors as Frantz Fanon, Malcolm X, Stokely Carmichael, C. V. Hamilton, and Sartre. In what follows, we limit our references to the writings of these men, and in spite of the many differences in their opinions, we shall refer to their strategy of conflict as that of the “New Violence.”

Comparing the Recent Norms of Violence with Those of *Satyāgraha*

A comparison of the maxims of contemporary violence-promoting leaders with those of nonviolence suggests that on the metaphysical level, it is not the oneness of all life or of humanity that is stressed, but a Lutheran dichotomy between the good and the bad. Certain groups regarded as comprising the good, brave, honest, and just are contrasted with exploiters, suppressors, liars, and traitors. There is, further, a theory of basic contrasts of interest: “[T]he colonial context is characterized by dichotomy,” Frantz Fanon asserts, and he continues:

The zone where the natives live is not complementary to the zone inhabited by the settlers. The two zones are opposed, but not in the service of a higher unity . . . they both follow the principle of reciprocal exclusivity. No conciliation is possible, for of the two terms, one is superfluous. (Fanon 1966: 31)

Power is considered largely to be in the hands of the “bad,” and since violence is taken to be the only adequate means of change, violence is necessary: Self-realization of the “good” group requires using violence against the “bad.” Complete self-realization of the “good” is impossible without violence against the “bad,” and killing does not prevent self-realization of the killer. On the contrary, it helps him. So even if brutality is in some sense “regrettable,” it is morally justified when considered as unavoidable.

From the point of view of Gandhi, the characterization of a human being as (categorically) bad is verbal violence. It denies the possibility of its increasing self-realization and thus justifies its treatment under certain circumstances as a nonliving thing.

As to the possibility of political liberation in the colonies, Fanon holds:

For the native, life can only spring up again out of the rotting corpse of the settler. (Fanon 1966: 72)

The native . . . is ready for violence at all times. From birth it is clear to him that his narrow world, strewn with prohibitions, can only be called in question by absolute violence. (Ibid., p. 31)

The future society envisaged by the advocates of violence seems, on the other hand, to be one of nonviolence and spontaneous conformity in opinions. (Pluralistic ideals are rare, and it might be asserted that this antipluralism is in its consequence a form of violence if conformity is not spontaneous.) Contemporary advocates of violence, in contrast to Fascist theorists, do not see violent activity as an end, but only or mainly as a means to obtain a new social order characterized by harmony and nonviolence.

The belief in such a transition implies a direct negation of a basic maxim of nonviolence, “The character of the means determines the character of the ends,” or in terms of our systematization, “The character of the means used in a group struggle determines the character of the results.” The “fanonization” of means will fanonize the emerging society. According to some advocates of the New Violence, however, the killer is free when he has killed the opponents. The past killing does not cast any shadow into the future.

Any amount, or a very substantial dose, of violence is consistent with a later realization of nonviolence, according to the principles of the New Vi-

NONVIOLENCE AND THE "NEW VIOLENCE"

olence, and some terror may even cleanse the soul and make the transition to nonviolence faster. Fanon considers short-term, preliminary, and immediate violence to be fully consistent with an emphasis on long-term universal reduction of violence. This certainly conflicts with Gandhi's hypotheses! It is in direct opposition to the hypothesis disclaiming that short-term violence may help: "Short-term violence counteracts long-term universal reduction of violence" (*H*₃, p. 63).

Destruction, sabotage, burning, and stealing manifest small-scale violence, and external expressions of and incitement to hatred are used as a means for strengthening the revolutionary resolve.

"Make a destructive program part of your campaign" (cf. *N*₂, p. 63) cannot be said to be a norm among the violence-promoting leaders, but the stress on "moral" encouragement by destruction of the bad is often present.

Physical violence is advocated by Fanon as a means of "burning bridges":

The group requires that each individual perform an irrevocable action. In Algeria, for example, where almost all the men who called on the people to join in the national struggle were condemned to death or searched for by the French police, confidence was proportional to the hopelessness of each case. You could be sure of a new recruit when he could no longer go back into the colonial system. This mechanism, it seems, had existed in Kenya among the Mau-Mau, who required that each member of the group should strike a blow at the victim. (Fanon 1966: 67)

Nonviolent actions strengthen the disposition for more (and stricter) non-violent action, according to Gandhi. However, there is, unhappily(!), no irrevocability. At any level, one may slide back to violence.

The radical distinction between antagonisms and antagonists (cf. *H*₄, pp. 66–67) is not accepted by Fanon. It would ruin the appeal to hatred and vengeance. Hatred against suppression is hatred of the suppressors, says a politician advocating violent revolution in South America.

The negation of the existence of interests that are common to all (cf. *H*₇, p. 67) plays a considerable role.

The intellectual who for his part has followed the colonialist with regard to the universal abstract will fight in order that the settler and the native may live together in peace in a new world. But the thing he does not see . . . is that

the settler, from the moment that the colonial context disappears, has no longer any interest in remaining or in co-existing. (Fanon 1966: 36)

Labor and capital, poor whites and blacks, these and other antagonists have no common interest of the kind that can furnish a basis for future co-operation (cf. *H*₈, p. 68). But in Kenya and many other places, a considerable percentage of successful white settlers remained in the colony after political liberation. Fanon's view on this point was historically not quite adequate.

The adherents of violent campaigns might subscribe to hypothesis *H*₉ (p. 68), that we invite violence from our opponent by humiliating him or provoking him, but this relation is taken sometimes to be a pro-argument for provocation and humiliation. In student demonstrations, premeditated provocation of the police and faculty plays a prominent role in many instances. We are reminded that theories of conflict can always be used in two ways: to exacerbate the potential of violence or to reduce it.

The Gandhian norm that you should move into the center of a conflict favors intensification of the conflict because you support the weaker part, the underdog. The norm implies a policy of confrontation, but not of provocation. The line may be difficult to draw, and there is in militant nonviolence always the risk of coercion and provocation. This practical difficulty, however, does not invalidate the distinction.

The student revolt has elicited what might be called "the new police violence" in many Western countries. The education of the police has not, until very recently, stressed nonviolence under strong verbal provocation ("pig!" etc.). The answer to such provocations is often what is aptly termed "unnecessary brutality." Official rules learned by the police in England and many other countries preclude physical or verbal violence as an answer to verbal violence from demonstrators. The officially sanctioned way of pushing or carrying people away from prohibited places does not involve physical violence. People are coerced—they are carried or (leniently) pushed "against their will." Theoretically such a procedure should not injure physically, and it should be tolerated insofar as one admits the authority of the police. If the number of police is insufficient to achieve the goal in this manner, the order to push or carry should not be given. The use of clubs to hit and injure is not an alternative. It would transgress the limits of police action (toward demonstrators occupying places without a warrant) and theo-

NONVIOLENCE AND THE “NEW VIOLENCE”

retically make the police part of a military force. The classical official doctrine of police action is a doctrine of nonviolence—with an exception, namely the rules for coercing without physical injury.

In nonviolent struggles in which the opponent has the necessary status to make free use of police forces, it is in the long-run interest to try to influence the police in the direction of consistent nonviolence. On certain occasions in the United States, such influence has prevailed. The police are, so to speak, interposed between the nonviolent fighters and the real opponent. To behave so as to make the police the main opponent is a grave misunderstanding of nonviolent strategy. The police and prison officers are important potential collaborators, in Gandhi's view, and the more contact with such people, the better. Confrontations are part of efficient communication; not so, provocations.

Secrecy of moves, keeping the opponent in ignorance, makes it possible to surprise him and enables one to retain the initiative, a prominent feature in today's violent struggle. However, this secrecy runs counter to the norms of (consistent, high-level) nonviolence (cf. H_{11b} , N_{11a} , pp. 69 and 75).

Journalists and reporters should be well received, but, of course, this does not preclude pestering them because of their distorted reports. The militant nonviolent fighter tries to keep informed about how actions are described in the mass media and tries to convert the reporters to his view. Secrecy stems in part from pessimism: reporters who have been against us cannot be turned into helpers. Fanon says:

Frequently reporters complain of being badly received, of being forced to work under bad conditions and of being fenced round by indifference or hostility: all this is quite normal . . . when a journalist from the West asks us questions, it is seldom in order to help us. (Fanon 1966: 60)

In a great many cases, Gandhi answered hostile journalists, but he was not always able to convert them into supporters. His failures cannot and should not change the strategy, but they reflect a major difficulty—getting time for in-depth discussions—and they remind one of the importance of constructive, direct actions. The mere sight of the place of action and the action itself should as often as possible suffice to reveal its aim. This makes long explanations unnecessary. If a campaign consists mainly of such actions, unfair reporting is difficult even if the journalists disapprove.

As to the quest for truth in general, Fanon stresses the impossibility of truthfulness in the colonial situation:

In every age, among the people, truth is the property of the national cause. No absolute verity, no discourse on the purity of the soul can shake this position. The native replies to the living lie of the colonial situation by an equal falsehood. His dealings with his fellow-nationals are open; they are strained and incomprehensible with regard to the settlers. Truth is that which hurries on the break-up of the colonialist regime; it is that which promotes the emergence of the nation; it is all that protects the natives, and ruins the foreigners. In this colonialist context there is no truthful behaviour. (Fanon 1966: 40)

According to the Gandhian hypotheses, truthful behavior in the colonialist context is not only possible, but has, in fact, been realized many times. The behavior of Abdul Ghaffar Kahn, first in India, then in Pakistan, furnishes many impressive instances. Furthermore, those hypotheses imply that there will be a transfer of untruthfulness from the colonial to the postcolonial struggles and also a transfer of narrow, pragmatic concepts of truth, for example, "Truth is what furthers *our* party in the struggle."

Perhaps the Gandhian concept of truth is also pragmatic, if not narrow too? In terms of our systematization, we might consider accepting the maxim "Good is what furthers universal self-realization." But the concept of truth as agreement with reality is conceptually independent of the good even if that maxim is adopted. Truth cannot possibly be a property of a national cause or any cause whatsoever, even the cause to further universal self-realization. The utilitarianism or pragmatism of Fanon and a great many others who are willing to give their lives for their cause is incompatible with the ethics of nonviolence. This ethics requires a concept of truth that is not dependent on causes. Truth cannot be monopolized by any cause whatsoever. The relation of this nonpragmatic conception to the aim of our pyramidal systematization is discussed on pages 56 f.

The question of truth, as Fanon sees it, is obscure. If an attack is made on a human dwelling belonging to a foreigner, the relevant questions are clear: Is anybody killed or injured? What relationships have those killed or injured to the goals of the campaign? What has been done to evacuate children? What has been done to influence the adults? To what use, favorable to the campaign, might the house be put? What will be the influence of the attack on foreigners in the neighborhood? On the attackers themselves? It is

on this concrete level that the sceptical attitude of Gandhi is relevant: Does this particular action lead to the short-term objective? What are the long-term effects? Could this or that particular case of burning or of meeting trust with distrust be avoided?

Systematic distortion of information and biased rendering of all moves by the opponent are of special importance in stimulating hatred and isolation and in tightening the cadres of fighters. Employing these techniques facilitates the formation of a homogeneous ingroup. The leaders must, of course, even according to Fanon, try to distinguish truth from (their own self-made) fiction, but it seems difficult to keep up an intensive flow of invectives without gradually beginning to believe in them or beginning to substitute propaganda for information. The case of Goebbels is a famous example of a man's ultimate surrender to his own propaganda.

Self-scrutiny and insight into one's own goals and motives make for less violent attitudes (cf. H_{12} , p. 69) provided there is a basic willingness to stand up only for causes one is confident are just. However just the cause, one's own motives are generally mixed. The resulting tension between belief in justice and one's own mixed motivation engenders for reluctance to use violence.

This way of reasoning may be foreign to Gandhi, however. He was aware of, and did not hide, mixed motivation as a feature of past campaigns, but it seems that he required the *satyāgrahin* to be able to answer yes to the question "Is my motive when starting this new direct action unmixed: is it limited to realizing the goal of the campaign or might it also involve a wish to injure the opponent or some other deviant motive?" The main question seems not to be whether motives are mixed or not, but whether, during the campaign, no irrelevant motive is capable of diverting the action from the path that is thought to be the best in order to reach the objective. A campaigner may, from very mixed motives, take a number of photographs of the opponent during a physical attack, but he will only make such use of them as is completely consistent with the goal of the campaign. A campaigner will in part for purely egocentric reasons try to avoid being maltreated, but he will try this within the limits of the norms of the campaign.

Your opponent is more likely to use violence if he thinks your case is unjust, and this he is likely to think if he sees his own point of view distorted and caricatured and your case described without regard to your actual, far-from-perfect behavior (cf. H_{13} , p. 70).

The term *fanonization* has been used extensively at universities where sporadic physical and constant verbal violence has colored the campaigns. The “establishment” has hit back with renewed structural violence. Communication among outgroups is often retained, and a fierce picture of the struggle with ingroups is often maintained.

The general convincibility postulated in H_{14} (p. 70) is denied in a fanonized struggle: some opponents are, and always will remain, uninfluenced, however good and just one’s cause. They are only impressed by “guns,” by force and threats. In such cases, it is of course considered time lost to try to convince the opponent.

It is surprising how such pessimistic views about the opponent crop up in practically every intensive struggle. Their influence just before and during riots or wars cannot easily be underestimated. They are used to justify the termination of conflict-resolving communication and to justify the absence of honest attempts to resume it after the breakdown.

The verbal violence on the campuses, especially the use of epithets and extreme accusations, is often an agreeable outlet of emotion and has little to do with those aspects of the interaction between the hostile groups that are causally effective. A wave of mutual accusations and denunciations may terminate seemingly without anyone admitting the correctness of any statement made by the adversary. Nevertheless, after some time, in a more relaxed atmosphere, some sort of solution or a compromise is arrived at on the practical level. The opposing groups have influenced each other, and their views have come to diverge less than before, but nothing of this is clearly admitted. The verbal violence perhaps functions as a secondary emotional gratification, making it easier to accept unwelcome compromises and ad hoc solutions with manifest drawbacks. If this is the case, the Gandhian purist would rather complain about a general lack of mental discipline (*brahmacarya*) than of serious violence. Some of the leaders of rebellion would concede this but point out that the lack of mental discipline is due to the frustrations caused by a thoroughly repressive system. One has to mobilize all who are willing to fight the system, whatever their level of mental discipline. If leaders were to demand acceptance of Gandhian norms, too few would partake in the fight.

It would take too much space to go through the rest of the norm system in our confrontation of Gandhi and the New Violence. Suffice it to say that the tendency to justify or accept violence leads to a thoroughly different conflict strategy from that of nonviolence.

What to Learn from the Reaction Against Nonviolence

Instead of pursuing a contrast of contemporary ideas of violent social revolution with nonviolent social revolution, we shall concentrate on certain basic similarities between the two ways of thinking and also on important necessary conditions or prerequisites of successful nonviolence today. The critique of postwar nonviolent campaigns has helped to remind us of such conditions.

The leading supporters of violence interpret the term widely. Their interpretation is at one point strikingly similar to Gandhi's use of the term, which includes suppression and exploitation under the concept of violence.¹ Open violence is contrasted to *structural* violence.

“*P* uses structural violence in relation to *Q*” may be thus defined: “*P* introduces or supports a set of coercive social relations that create barriers against *Q*'s complete self-realization.” The coerciveness usually depends on a judicial system that can threaten *Q* if he rebels against the suppression. The social relations usually have an economic character, but conceiving of them as fundamentally economic leads to narrowness of perception.

The definition does not, of course, furnish us with a clear concept, but it seems to cover an important use of the term *structural violence*, and it connects with the metaphysics of *satyāgraha*. One weakness of the definition consists in the tacitness of the assumption that the barriers are objectively unnecessary, that is, that economic and other conditions are such in the society in which *P* and *Q* act that one could afford *Q* the higher degree of self-expression made possible by lifting the barriers. In order to clarify this assumption, we would have to introduce a large portion of contemporary (highly controversial!) sociological and economic conceptual theory.

Absence of manifest physical person-to-person violence is not enough to characterize a relation as nonviolent, according to theorists of the New Violence. Barriers to complete self-realization or, more precisely, to a degree of self-realization deemed practically realizable given certain existing economic and technical resources are taken to indicate conditions of violence. The economic underdog–top dog relation is taken equally seriously by Gandhi and the new leaders of violence as a kind of violence (*himsā*). Gandhi once even called exploitation “the essence of violence” (*Harijan* 4.11.1939: 226; quoted in Prabhu and Rao 1967: 369). However, there are also other similarities.

The criticism of past nonviolent campaigns concerning race relations has centered around the slowness of the machinery and the timidity and modesty of their claims. Nonviolent movements in the United States have not until recently asked for “justice now.”

Gandhi at least sometimes asked for immediate basic changes. In 1942, he started the “quit-India!” campaign — one of his least successful, perhaps — but not untypical of his impatience and “immodesty”; it reflected his belief in the practical possibility of, as well as the immediate need for, a rapid radical change, that is, a nonviolent revolution. Appeals to students to leave the colleges and fight for freedom are examples of actions based on a requirement of rapid change. What made Gandhi sometimes choose rather modest targets was the very realistic suspicion that the Indian populace was far from ripe for taking over the institutions led by the British. Further, what made him sometimes cancel campaigns was the also realistic suspicion that the population was not yet sufficiently nonviolent, which means that they would not be able to achieve what Gandhi saw as the goal: a non-violent society.

But on the whole, revolutionary impatience is something the new leaders of violence have in common with Gandhi. It is also a point where he differs from Martin Luther King, Jr. and some of the other great civil rights personalities. Gandhi had a toughness and disregard for bloody confrontations that many Christian pacifists felt bordered on savagery.

There is still another similarity: the brutal Gandhian norm “Seek the center of the conflict” or, more generally, the stress on activist confrontations with the system. Gandhi strongly resented passivity or mere verbal support of fighters, and he emphasized how participation in direct action radicalizes.

The new tendency is to proclaim that things cannot continue as they are, radical change must come immediately; no one can be allowed to remain passive. Polarization of opinion, however painful, is necessary. Further, with the present productive capacity and manpower, a just and nonviolent society can be realized.

Some of these points reveal the stress on antagonisms, on structures rather than on antagonists. This stress is a main feature of Marxist thinking. Certain antagonisms must immediately be eliminated — but without necessarily eliminating any of the antagonists.

As a consequence of proclaiming it a duty to act vigorously and immediately, the new leaders, just as Gandhi, engage in lively direct agitation and

NONVIOLENCE AND THE "NEW VIOLENCE"

preaching at the grass roots, refusing to be hampered by democratic machinery. If the machinery is ill equipped to cope with large-scale injustice, direct action must be resorted to. Gandhi did not try to quell communal riots through laws and parliamentary action.

Indian nationalist politicians of the Congress Party accepted Gandhi as a leader because of his unrivaled influence among the masses, at the grass roots, but there was always uneasiness about his relation to the party system and later to the whole parliamentary setup. It suited neither his temper nor his philosophy.

There is, in Gandhi's view, nothing sacred about the electoral or legal system. Yet there is, of course, a grave responsibility associated with suspending or violating the system. Every plan to break a law must be thoroughly discussed and illuminated before its implementation.

The Basic Requirement of Self-Respect: Fearlessness

When Gandhi left South Africa and started work in India, he realized that the masses in India could not immediately be mobilized to political action for independence, for *svarāj*.

From prolonged hunger or undernourishment apathy follows. Gandhi sometimes complained that the most frustrating thing of all was the unwillingness of the hungry to do anything to change their own personal lot. He found that the basic obstacle when trying to mobilize the masses was their feeling of powerlessness, uselessness, and insignificance. From this attitude there follows a lack of personal identity and personal norms and, of course, lack of initiative to find ways of producing more and better food.

Gandhi was unable to effect any radical change in the food situation; he could not eliminate undernourishment and unemployment. However, in spite of this, he managed to awaken the masses and to mobilize them. How? One of his greatest inventions was the Khadi.

The Khadi movement and certain similar undertakings had a variety of aims. But one basic aim was precisely to get the poor, unemployed, suppressed, and passive to realize that they were persons with an identity, a dignity; they were worth something, and they were not completely helpless.

At this point, it might be inserted that political opponents of Gandhi described the Khadi movement as if it were Gandhi's complete answer to In-

dia's economic crisis. This way of misconceiving the movement was repeated in a well-known article by the author Arthur Koestler in the *Sunday Times*, October 5, 1969. But Gandhi did *not* nurture "the fantastic hope of solving India's economic problems by bringing back the handloom and the spinning wheel." He had great confidence in intensive agriculture, including irrigation, using refined machinery. He had less confidence in industrialization as a means of overcoming poverty and lack of work in the villages. The increasing flow of the unemployed toward great cities created terrible problems. The ugly riots were all starting in the big slums. Gandhi saw the necessity of creating conditions such that people could on the whole remain in their villages except for the few that big industry would need. Indian Marxists were squarely against his economic views, being convinced that the proper course of India was the one followed in Soviet Russia in the years after the revolution, that is, immediately giving first priority to heavy industry. The correctness of this policy is now much disputed, but its advocates in the 1920s and 1930s of course found Gandhi's stress on agriculture insufferably reactionary.

Gandhi's propaganda for the spinning wheel was first of all a successful campaign against the total passivity and resulting lack of self-respect of the very poor. Making their cloth meant for thousands of jobless wretches the start of a new kind of life and participation in a national struggle for liberation. Marxists at that time were very much against the religious aura surrounding the spinning wheel, and the poet Tagore detested the frenzy of the campaigns.

If a hundred or two hundred million underfed and more or less jobless villagers in India were to try to get industrial work in the cities, what would happen? "Heavy industries will need to be centralized and nationalized. But they will occupy the least part of the vast national activity which will mainly be in the villages" (cf. Gandhi 1951c). He had "no partiality for return to primitive methods," but village industry was the only "way of giving employment to the millions who are living in idleness." Gandhi went perhaps too far in his fight for decentralization and against the creation of big proletariats, but recent developments in the West have made Gandhian value priorities worth serious study.

The participation of the poor and underprivileged in the Khadi movement and vigorous campaigns such as the salt march, with obvious, spectacularly direct relevance for their economic well-being fostered that minimum

NONVIOLENCE AND THE "NEW VIOLENCE"

of self-respect indispensable for meaningful participation in nonviolent campaigns. One may say that Gandhi's strategy included as a preliminary step the lifting up of people from the status of nonentities to a level at which self-realization was conceivable as an aim. Only on that level could self-discipline, born of self-respect and dignity, be reckoned upon under harsh provocations and frustrations. Self-respect, in short, is a prerequisite for non-violent mass campaigns.

Martin Luther King, Jr. was completely clear about the basic function of self-respect in struggles for liberation:

With a spirit straining toward true self-esteem, the Negro must boldly throw off the manacles of self-abnegation and say to himself and the world: "I am somebody. I am a person. I am a man with dignity and honor."

(King 1967: 43–44)

However, to exhort a black man in the ghetto who does not feel he is somebody to boldly tell the world "*I am* somebody" is not a meaningful strategy. The strategy had to be one of leading black people from "nothing and nowhere" toward a point at which they could honestly say "I am somebody." Only then may the process start of boldly throwing off all the signs of slavery. "Psychological freedom, a firm sense of self-esteem, is the most powerful weapon against the long night of physical slavery," says King (see p. 115). Yes, but that weapon must be forged, and those who do not have that firm sense of self-esteem are precisely those who cannot do the forging by themselves.

Gandhi and King both faced the question of creating self-respect, but it seems that Gandhi may have been more inventive in his choice of methods or that the social and cultural condition of the Indian peasants was in certain senses better than that of the American blacks in their ghettos.

Violence Preferable to Cowardice

Fearlessness is indispensable for the growth of the other noble qualities. How can one seek Truth, or cherish Love, without fearlessness? (Bose 1948: 24)

Gandhi held fearlessness to be a necessary condition for all other high qualities. It has a position in his system that can only be justified by linking it

closely to necessary conditions of self-realization and therefore of active search for truth.

To run away from danger, instead of facing it, is to deny one's faith in man and God, even one's own self. (Prabhu and Rao 1967: 144)

If a person is not willing to take risks, he will not follow any insight, any personal conviction if it seems dangerous to do so. Lack of fearlessness Gandhi likes to call cowardice, even if this lack is rather modest and quite common.

The long road toward nonviolence cannot be followed, according to Gandhi, if one does not fight cowardice—even when it entails acting with violence. Some quotations are needed in order to develop his somewhat complicated views on this point.

I found, throughout my wanderings in India, that India, educated India, is seized with a paralyzing fear. We may not open our lips in public; we may not declare our confirmed opinions in public. . . . [I]f you want to follow the view of Truth in any shape or form, fearlessness is the necessary consequence. . . . We fear consequences and therefore we are afraid to tell the truth.
(YMCA address, "The Vow of Fearlessness," 1916;
quoted in Prabhu and Rao 1967: 308)

I do believe that, where there is only a choice between cowardice and violence, I would advise violence.
(*Young India* 4.8.1920: 5; quoted in Prabhu and Rao 1967: 142)

Critics of King stress that a man who lacks self-respect and self-identity cannot—or at least cannot be expected to—refrain from violence when met with violence, except out of cowardice. His reflexes answer violence with violence; the question is only, Do I dare? King and pacifists in general have tended to reject counterviolence at the same time as they have deplored cowardice.

It is the choice between violence and cowardice in such cases that the Black Power critics (in the wide sense of the term *Black Power*) tell us characterizes the situation for the majority of black citizens in the United States. They meet daily structural discrimination and structural violence.

If the choice between violence and cowardice is constantly repeated and if the victim of violence answers every time to "Dare I?" by turning

NONVIOLENCE AND THE “NEW VIOLENCE”

away — avoiding the conflict or meekly turning the other cheek — a cowardly attitude is reinforced. The chance of standing up next time and of hitting back decreases. In the long run, the chances of standing up in any way whatsoever decrease.

This kind of description by the Black Power leaders not only reminds us of similar descriptions by Gandhi; it follows Gandhi's utterances word by word.

The new leaders exhort their poor followers to hit back if insulted. Compare this with Gandhi:

If you feel humiliated, you will be justified in slapping the bully in the face or taking whatever action you might deem necessary to vindicate your self-respect. The use of force, in the circumstances, would be the natural consequence if you are not a coward. But if you have assimilated the non-violent spirit, there should be no feeling of humiliation in you. (*Harijan* 9.3.1940)

One might add that the person with nonviolent spirit does not feel humiliated by insulting behavior on the part of others because his self-respect nullifies the effect of the insult. The insulting words or deeds simply do not impress him, and he naturally does not feel any smaller. There is no feeling of shame, of reduction in status, of loss of dignity. It is the aggressor that loses in dignity, not the so-called victim.

The quotation makes a priority clear: of the two goals “Stop conceiving of yourself as humiliated” and “Stop answering violence with violence,” the first is prior. Only when the first goal has already been reached can the second be accepted unconditionally.

The quotation is not only significant as one among dozens of clear statements assessing the negative value of cowardice as greater than the negative value of violence; it is also one of the few but clear indications of the immense importance Gandhi attached to self-respect. Faced with a potential loss of self-respect, it is the prime concern of the individual to avoid the loss. Loss of self-respect must be avoided even if the only way to do it, as perceived by the individual, is to be violent, to be criminal, to murder. This seems to be the consequence of Gandhi's remark on humiliation and violence.

How can Gandhi justify going to such extremes? The answer is that without a minimum of self-respect, of inner security, one cannot even reach the road leading toward self-realization, and this again means that one can-

not start on the road toward nonviolence. That road takes off from the road toward self-realization, not vice versa. The man feeling he is nobody, a no-person, may help himself to be somebody by acts that cannot be tolerated by mature persons.

An important lesson expressed by the quotation can be summed up as follows: participants in a conflict perceive the situation differently according to their level of self-respect. At a very low level, the behavior of the opponent is likely to be experienced as humiliating and provocative. To let oneself be provoked indicates loss of self-respect and admission of powerlessness. At a higher level, with higher degrees of self-security, no violent behavior of the opponent is experienced as humiliating, and none as provocative. Then, one's own violence may be experienced as humiliating, not that of the opponent. A concentration camp guard tends to believe that when a prisoner is forced to creep through mud in front of hundreds of his fellow inmates, the prisoner loses dignity and self-respect, whereas the witnesses only see the loss of these qualities in the guard.

In India, Gandhi succeeded to an unprecedented degree in raising the weak masses to a substantial level of self-respect. They were made capable of following a leader. The magic spell of Gandhi was even stronger than the imperative force of a man in uniform swinging a formidable club (*lāṭhī*) and throwing people in jail. But, of course, nonviolence never matured into a deep-rooted power in India. Provocations such as those experienced in the years 1946–48 proved too strong, and there was a lapse toward large-scale violence among the masses.

In the United States, the urbanized blacks did not feel they had a living cultural tradition strong enough to furnish a source of self-respect and nonviolent power. When Martin Luther King, Jr. began his bus campaign in 1955, mobilizing fifty thousand blacks, he seems to have started with masses on an even lower stage of development of self-respect and dignity than did Gandhi when in April 1919 he inaugurated his all-India *satyāgraha* movement to secure withdrawal of the Rowlatt Bills. Black Power leaders have proved to possess a keen eye for means of raising the level of self-respect. Thus, their demand for large-scale instruction in African culture at schools and universities shows their deliberate effort to give their followers inner security. The propaganda for African hairstyles, clothing, and other external signs of pride in being black manifest the same tendency.

Violence as a Means to Increase Self-Respect

Whatever the causes, King and his faithful followers did not succeed in mass mobilization on a continental or subcontinental scale. Wonderful feats of nonviolence under brutal attacks and supreme personal achievement in civil rights cases could not make up for the lack of mass support. Impatience grew by leaps and bounds, and the cry for immediate, radical change was heard more and more often. It issued from people who knew the potentialities of nonviolence: "[Y]ou know history has been triggered by trivial-seeming incidents. Once a little nobody Indian lawyer was put off a train, and fed up with injustice, he twisted a knot in the British Lion's tail. *His* name was Mahatma Gandhi!" (Malcolm X 1965: 272). But they did not believe in the prospect of consistent nonviolence in the crisis of race relations.

Now, what the Black Power leaders have done is essentially to tolerate and to some extent encourage counterviolence, to hit back when hit; and it is my hypothesis that the subtle, not always conscious, but strong motive has been that of building up self-respect, a sense of dignity, and a feeling of inner security. There have, of course, been mixed motives, and the expressed aims testify to this; but there is enough evidence and material, verbal and nonverbal, to maintain the self-respect theory of Black Power violence.

Incidentally, Sartre seems (in his preface to Fanon's book) to agree with Black Power leaders on the function of counterviolence:

The native cures himself of colonial neurosis by thrusting out the settler through force of arms. When his rage boils over, he rediscovers his lost innocence and he comes to know himself in that he himself creates his self. Far removed from his war, we consider it as a triumph of barbarism; but of its own volition it achieves, slowly but surely, the emancipation of the rebel, for bit by bit it destroys in him and around him the colonial gloom. . . . [T]o shoot down a European is to kill two birds with one stone, to destroy an oppressor and the man he oppresses at the same time; there remain a dead man, and a free man. . . .
(Sartre in Fanon 1966: 18–19)

Fanon puts it in this way:

At the level of individuals, violence is a cleansing force. It frees the native from his inferiority complex and from his despair and inaction; it makes him fearless and restores his self-respect.
(Fanon 1966: 73)

At a deeper, psychoanalytic level, Erik H. Erikson traces the connection between Fanon's killing and the basic Gandhian hypothesis that violence against the other is violence against oneself (cf. *H₄, p. 48):

That killing, in fact, may be a necessary self-cure for colonized people was Dr. Frantz Fanon's conviction and message. . . . An implicit therapeutic intent, then, seems to be a common denominator in theories and ideologies of action which, on the level of deeds, seem to exclude each other totally. What they nevertheless have in common is the intuition that violence against the adversary and violence against the self are inseparable; what divides them is the programme of dealing with either. (Erikson 1969: 74)

King, in a quote cited earlier, puts it in a slightly different way:

With a spirit straining toward true self-esteem, the Negro must boldly throw off the manacles of self-abnegation and say to himself and the world: "I am somebody. I am a person. I am a man with dignity and honor." (King 1967: 43–44)

Showing his understanding of the basic function of self-respect in the struggle for liberation, King continues, as cited earlier (p. 110):

Psychological freedom, a firm sense of self-esteem, is the most powerful weapon against the long night of physical slavery. (Ibid., p. 43)

Our contention is that a minimum of self-esteem is a necessary condition for nonviolent as well as violent struggle and that no exhortations but only action can help to create that minimum requirement if it is absent. The critical question, however, is, Must the action be violent? Gandhi's answer is no, that of Sartre and Fanon, yes.

One is justified in concluding that none of the tough Black Power leaders take physical violence to be more than a preliminary to more constructive efforts. The mental violence—abuse, vilification, distortion in words—will perhaps remain popular as an outlet, but sooner or later constructive efforts will be seen to suffer disproportionately from the hot flow of verbal provocation. There will probably be a tendency toward nonviolent noncooperation and the building of parallel institutions, at least in the economic sector. The war of words and small-scale, unorganized, personal aggressiveness will be found to be uneconomical, too costly, if not degrading, and undig-

nified for race-conscious blacks who clearly see that such tough behavior is characteristic of the whites they despise.

Our aim has been to describe and compare different points of view, not to offer criticism. Perhaps it will therefore be not entirely inappropriate to make a small personal comment: we agree that nonpremeditated, spontaneous violence is sometimes a cleansing force. However, the cleansing force is dependent on spontaneity. Premeditated violence instigated by gang leaders and supported by articulated group norms is scarcely a cleansing force. Therefore, the policy of violence, deliberate plans to use violence as a means in certain group conflicts, cannot be vindicated as a means of creating self-respect. Nor does this policy seem able to solve the long-range problems King had in mind. Furthermore, Black Power leaders tend to defend violence mainly as a desperate means to protect themselves individually against murderous police forces. We thus return to the nonviolent approach, but with a better understanding of the indispensability of constructive programs and an appreciation of the necessity of efforts to increase self-respect among the weakest groups.

Satyāgraha Is Not a Set of Techniques

In a description of Gandhi's *satyāgraha*, one error has perhaps been more damaging for adequate understanding than all the others put together: the description of *satyāgraha* as a mere bundle of techniques. A central characteristic of a technique is its pure instrumentality, its character of being a mere means to an end.

Consider the technique of shooting: a gun may be used by anyone with sufficient know-how. Its use may be quite independent of the thoughts and motivation of the person using it. But this is emphatically not the case with nonviolence. For an action to be part of a nonviolent campaign, it must conform, at least roughly, to the norms and hypotheses characteristic of nonviolence, these being the conscious expressions of nonviolent behavior, attitudes, and institutions. The normative system implied may, of course, be conceived in somewhat different ways and one may have different degrees of approximation to an ideal campaign. However, the techniques, described in terms of overt behavior, cannot be detached from the characteristic norms and hypotheses. A strike, a stay-at-home, or a fast, described in terms of behavior, are not yet instances of *satyāgraha*. They must conform with norms and hy-

potheses of *satyāgraha*, and they are therefore unsuccessful if the opponent or the general public perceives only the behavior, not its symbolic aspect.

Joan Bondurant and others have tried to compare levels of purity of nonviolence in different campaigns. One must, of course, allow for practical errors of judgment and some transgression of norms, but there is less room for variation in intention. If there is no serious resolve to act nonviolently, following most of the norms, this has immediate consequences for how one appears to and is interpreted by the opponent. It is in most cases easy to detect superficiality. One of the most ruinous attitudes is that of trying out nonviolence, and, if that does not lead to success, intending to use violence. This strategy leads to a head-on collision with the norms and hypotheses of nonviolence. The thought “I shall first be nonviolent, and if it does not succeed, I am justified in using violence” is contradictory. There can be no such first-stage nonviolence.

The (implicit, rarely explicit) rejection of *satyāgraha* by the leaders of the New Violence is based in part on this misleading picture of *satyāgraha*: black people are described as partaking in a march or other action as if the external behavior were identical with the action of *satyāgraha*. The picture lacks a description of a positive content of the action itself, its goal-revealing aspect. Furthermore, the attitude of black people is described in terms of humiliation and passivity: their being abused, hit in the face without their “doing anything.”² They have also been described as obsessed by fear and hatred all along. Their church is burned; what shall they do? Nothing, according to certain black-leader descriptions of the nonviolence of Martin Luther King, Jr.

From the preliminary definition of a *satyāgraha* campaign as a campaign consistent with, and expressive of, a nonviolent system of norms and hypotheses, it immediately follows that *satyāgraha* is not a technique. The inclusion of hypotheses is essential; one cannot be asked to believe in certain hypotheses as part of a technique. The technique of firing a gun is independent of any beliefs concerning the meaning and consequences of the behavior involved in firing it.

Individuals are not simply masters of their own beliefs; they cannot normally adopt and reject beliefs according to the needs of the moment. Insofar as they are able to do this, they violate the requirements of truthfulness. Nor can they believe in a norm, or respect it, as part of a technique. But they can believe in norms and hypotheses as part of a total creed and develop

techniques of action that are consistent with, and expressive of, this creed. Thus, they may be asked to break a law, to distribute food, to carry a banner, and so on, as part of a campaign expressive of a creed. If the creed is absent, they cannot do what is asked.

To call *satyāgraha* a method rather than a technique is less misleading because the etymological meaning involves that of *a way* of acting or living. But if a nonviolent campaign is said to be a way of planning and carrying out a campaign, it is only a way that can be adopted by persons who share certain beliefs and attitudes. The confusing point about this terminology is that some of these beliefs and attitudes are part of “the way.” Thus, in discussions in which theoretical clarity is at issue, *satyāgraha* should not be classified only as a method or way of struggle or conflict solution.

How much is required of shared beliefs depends on one’s role in the campaign. Gandhi expected much more of a leader and strategist than of a follower. Confronted with the hypotheses characteristic of belief in *satyāgraha*, many people, including military leaders, will hesitate to squarely reject or accept them as true or as convincing or highly probable. Uncertainty prevails as to their relative validity or invalidity. It therefore makes sense when military leaders or others who traditionally support institutions of violence favor experiments in *satyāgraha*. They favor its tentative use in various kinds of situations. It makes sense insofar as it is a reasonable way of testing the hypotheses that the *satyāgrahin* assert with some dogmatism. However, those engaged in mere testing are not yet *satyāgrahin*. *Satyāgraha* cannot be used properly because it is not a technique, not an instrument.

This point is of importance because the opponent cannot be expected to be impressed by an appeal to the brain and the heart, when the appeal is an *experimental* appeal, a test of power. The difference from a genuine appeal is all too clear in face-to-face confrontations. An appeal to the heart is expected to come from the heart, not from the brain of the experimenter.

The mistake of taking *satyāgraha* to be a technique is, of course, not as widespread as the tendency to use the word *technique* for it. Some of the theoreticians (Bondurant and others) who use the word make it clear that it is not a technique in the sense of a mere instrumentality, independent of the convictions and attitudes of the user. The various activities involved in *satyāgraha* may contain the use of techniques—for instance, making salt, spinning, preparing meals, beating drums, singing songs, building houses, and operating banks. But these are not characteristic of the *satyāgraha* as a whole.

The lighthearted use of the term *technique* and the neglect of systematic study of the roots of nonviolence in ethics and metaphysics has facilitated an incorrect classification of some political, racial, and student campaigns as nonviolent. Demonstrations, strikes, and fasts have been classified as Gandhian and conceived as nonviolent when they have only avoided manifest physical violence. Their lack of success, however, often seems to be due to their neglect of the basic norms of Gandhian struggle.

Isolated traits of Gandhian conflict behavior have been studied from the point of view of game theory. Thus, R. E. Klitgaard uses “two-party conflict models” to study *satyāgraha* “as a tactic” (Klitgaard 1971: 143). He does not deny that it is sometimes a successful tactic but finds that it contains “many contradictions and inconsistent strategic implications” (ibid., p. 152). This is hardly surprising. What is lamentable is the more or less implicit assumption that one has to either think of Gandhi as a tactician or treat him as a saint and refrain from analysis. Gandhian conflict behavior must be studied in relation to a norm system. Any analysis solely in terms of tactic, technique, or method must lead astray.

The Use of Violence as a Sign of Impotency

As systematized by our set of norms and hypotheses, any kind of violence in any kind of conflict situation violates at least one norm. Violence is never right. One may quote Gandhi in support of this unrestricted condemnation. But, as is very well known and has been extensively discussed since the time of the Boer War, Gandhi gave his moral support to groups engaged in war or other violent conflicts. Furthermore, he accepted, recommended, and justified the physical violence to, and injury of, human beings. He has even postulated it as a duty under certain circumstances for certain persons to use physical violence against opponents. This last duty seems to flatly contradict norm N_3 (p. 63), never to resort to violence against an opponent.

There is no easy way of bringing consistency into this seemingly confused aggregate of sayings and actions. The least intricate way, in our opinion, is to take the consequences of three facts:

1. Gandhi’s acceptance, recommendation, vindication, and “duty-postulation” of an act of violence occurs only in relation to a definite person or (small) group of persons.

NONVIOLENCE AND THE “NEW VIOLENCE”

2. The persons by whom the violence is positively (or at least not negatively) valued are in a state of impotency and manifest helplessness. They are at least momentarily not able to follow the norms against physical violence.
3. For such persons it is an inescapable duty to act immediately in the situation in which they find themselves — to act in support of a manifest, high-level goal.

The state of impotency does not have as a consequence a rejection of the system of nonviolence, but the system is nevertheless violated by these persons; they create an evil. However, the evil does not discredit them as persons. It is rather their lack of foresight, their lack of training in nonviolence that is discreditable.

There are, for these persons, ethically meaningful questions to be asked: What can I, should I, or must I do, being in a momentary state of impotency? Gandhi has some answers to these questions. They are not part of his teaching on nonviolence, and they cannot be made part of its systematization. They nevertheless lie within the framework of his total ethics. The ethics of group struggle, as portrayed on pages 53–57 does not take into account comparisons of evils, that is, ethically valid judgments of the kind “A is a greater evil than B.” A person in a state of impotency may have to decide to create evils, but his attempt to create a minimum is in this situation laudable, not damnable. The act does not discredit the person. On the other hand, the state of impotency may be due in part to the neglect of training in nonviolence. It was a recurring lament of Gandhi’s that the Hindus neglected this training and that the politicians of the Congress Party did not support his plan of nonviolent brigades in every danger area of religious conflict. The frequent clashes between Hindus, Muslims, and Sikhs would give ample training in nonviolence. This would minimize the chance of situations of nonviolent impotency.

In conclusion, we may say that Gandhi did not condone violence in any situation. Violence, not specified as the violent act of a definite person, is as such always an evil. On the other hand, given a definite person in a definite situation, an act of violence committed by that person sometimes justifies our saying, “N. N. acted correctly,” “It was a duty of N. N. to act as he did.” The terms *correct* or *right* and *wrong* attach here directly to the person: “The

person was right in doing so-and-so," "It would have been right for any other person in this state and in this situation to act as N. N. did."

This way of looking at the matter not only brings formal consistency into the teaching of Gandhi, but shows how naturally the seemingly contradictory maxims can find their dwelling within one person.

Gandhi's Notion of Nonviolence: Axiology or Deontology?

The claims made by the norms of our systematization are *deontological*: they say what must or should be. One such claim is that anyone should do as the norms tell. There is no gradation: either you should do it, or it is not the case that you should. *Tertium non datur*. In a value system, there is gradation. Some values are taken to be higher than others, a relation not to be confused with that of derivation.

It is tempting to solve the problems Gandhi poses for the systematizer by recommending violence under some circumstances by taking "courageous defense of the helpless, whether nonviolent or violent" as a higher value than "abstention from violence because of cowardice."

The axiological view might be formulated as follows: "Values are worth realizing, but there is a hierarchy of values, there are priorities, in both the positive and the negative realm." Thus, the most important function of grading positive and negative values in making a conceptual reconstruction is to make precise what to do under non-ideal conditions, especially when the shortcomings taken for granted are those of humans.

It follows that the unconditional abstention from violence is, strictly speaking (according to Gandhi), only the highest realizable value for a definite person *P* in a definite situation *S*, provided *P* is not a firm believer in violence in *S* or provided *P* is a coward (is dominated by fear in *S*). If *P* is dominated by fear, he should act violently rather than run away. And if he is convinced that an act of violence is the only possible means of reaching a (good) end in *S*, he should perform the violent deed.

In these sentences, we have used deontological language ("should") together with axiological ("best"). The complications resulting from Gandhi's outlook on cowardice may be addressed with a normative, deontological system, but it is much more convenient, even natural, to use an axiological system. A person who in *S* behaves nonviolently and fearlessly is realizing a

higher value (his behavior is better) than a person who in *S* behaves violently and fearlessly. Further, this person is again acting more valuably than one who acts nonviolently out of cowardice. Of the three values, two are positive and one negative. The less high value is positive insofar as the action is recommended in certain situations. If Gandhi even goes so far as to make it a duty to act violently in certain cases, a positive value must in those cases somehow be realized by the violent action.

Grave consequences, however, flow from the axiological approach. According to this interpretation, it is not sentences of the form "If *x*, then use violence" that reflect Gandhi's thinking, but rather those of the form "If you cannot do what you should do, prefer violence to cowardice." In this sentence it is implied that what you do is wrong. This is very different from the point of view of the performatory use of language, which implies that what you do is the next best or next to the next best. According to Gandhi, (1) there is no definite limit to the strengthening of one's nonviolent capacity, and (2) one is not permitted to calculate beforehand what one might not be able to do nonviolently in a future situation. Gandhi did not argue that we could decide on the limits of our capacity for nonviolence well in advance of a particular, acute conflict situation. "Impotency is avoidable." This hypothesis is taken to be valid until the conflict situation is present physically in the form of a threat to persons who are obviously too weak to resist direct physical attack. In such situations the *satyāgrahin* may be justified in proclaiming that he is in a state of impotency, and it may be his duty physically to attack the aggressor.

In conclusion, we shall retain the deontological approach. We shall also speak of degrees of wrongness, weakness, and error and distinguish degrees of the seriousness of breaks with norms of nonviolence. However, we shall not try to incorporate norms such as "Be violent rather than a coward" into the norm system.

When heavily exploited, some people today resort to physical violence, while others respond with widespread indignation and a warning to resort to legal means. If we take the term *violence* to cover any avoidable severe curtailment of the possibilities of self-realization of others, the indignation is misplaced if not accompanied by a parallel indignation at the structural and sometimes physical violence suffered by those who are being exploited. As it is now, the outcry is rather one of "How dare you do violence!" instead of "How dare we remain passive!"

Constructive, Goal-Revealing Campaigns

Gandhi was a great believer in person-to-person contact. He was a believer in the possibility of showing, rather than telling, the opponent what a campaign aims toward. Excepting the Khadi movement, he did not take very seriously the talk about campaigns and the glorifying accounts of their implementation. He expressed a low estimation of the function of his periodicals *Harijan* and *Young India*. He did not deplore their suppression! He thought that a campaign would have a stronger appeal when it showed what the campaigners wished to realize than when he talked about it. To him, a campaign would be more powerful when it showed the positive future state of affairs (untouchables praying in temples, making salt) than when it showed the present negative state of affairs (the clubbing of campaigners, pictures of fat rich people, and so forth).

The requirements or ideal of constructivity favor the establishment of parallel institutions and parallel business. This is the main reason why the slogan “Take care of business” (T.C.B.) may be regarded as the indirect offspring of the nonviolent campaigns in the United States.

Stokely Carmichael and Charles V. Hamilton conclude their book *Black Power* with the following highly relevant proclamation:

[W]hatever the consequences, there is a growing — a rapidly growing — body of black people determined to “T.C.B.” — take care of business. They will not be stopped in their drive to achieve dignity, to achieve their share of power, indeed to become their own men and women — in this time and in this land — by whatever means necessary. (Carmichael and Hamilton 1967: 184–85)

The work in parallel institutions can go admirably hand in hand with other parts of a constructive program. Selfless work is needed in order, for instance, to build and operate a cooperative or a school.³ Teachers may perhaps not get a decent salary in the first year but will they be “ruining” their careers? There is ample opportunity for constructive suffering.

Gandhi tried to implement the formation of parallel institutions, but not with great success. Some of the basic parts of the constructive program, such as help for the untouchables and the Khadi, exhausted most of the available energy of his followers. There was not much left for building schools, establishing law courts, and so on.

NONVIOLENCE AND THE “NEW VIOLENCE”

In the case of the salt *satyāgraha*, the manufacturing and storing of salt and its distribution to the poor were all positive measures consistent with a T.C.B. norm.

Struggle by means of constructive campaigns seems to have a great future in societies with a fairly high level of personal, not necessarily private, enterprise. With sufficiently widespread public support, almost anything can be realized by a simple resolution to act as if an institutional change were already realized. This holds well, for instance, in educational institutions.

Central authorities may stop financial support of one rebelling school, but if nearly all schools are radically changed by teachers and students, it is unlikely that financial support can be stopped.

If a tiny group favors a radical institutional change that the rest of the community ignores or considers worthless, the conflict is, of course, of a very different kind. The small group must somehow get the rest to pay attention and reconsider, and at that moment, acts of violence are (in many countries) more likely to get reported in the mass media than anything else.

Does the constructive approach go against those who ask for an immediate and radical change in society, a change that destroys all present institutions? Not necessarily. A judicial system is destroyed by not being used by anyone; the same holds for voting. If an institution is left to die because a completely different one is being created, there is a radical constructive, not destructive, change. There is no limit to the application of the approach; but inertia makes it highly improbable that old institutions can be destroyed overnight. The experience of Mao Tse-tung is a recent grand-scale manifestation of this point. On the other hand, physical destruction also has limited consequences. All prisons might be blown up without the prison system being affected. New, more solid prisons may be built, and the sale of dynamite curtailed!

In short, the maxim “The whole system must be destroyed” does not rule out constructivity. What rules it out is the addition “before we can think of what might replace it.” No definite new system may be needed, but new mores are at least required in a radically changed situation.

Constructivity and Destructivity in Gandhi’s Salt *Satyāgraha*

Constructivity—the visual, concrete, clear manifestation of goals—is of the utmost importance when trying to solve the constant problem of com-

munication with immediate opponents, for instance, with the police and soldiers (national guard and so forth). In severe conflicts, the *satyāgrahin* is not confronted with an antagonism, but with physically present antagonists. The antagonist directly in front of him may not even know about the antagonism.

Let us take the salt *satyāgraha* as an example, clearly announced to the viceroy in the famous letter of March 2, 1930. To march 241 miles is in itself communicative only as proof of persistence, will, and stamina. But the salt march was one from Ahmedabad to the sea, where it was announced that salt was to be made from seawater.

The direction of the march plus the culminating manifestation, the easily understandable making of salt, made the salt march positive and indicative of the goal of the campaign. Compare this with the poor people's march to the bureaucratic center in Washington, D.C. What were they to do in Washington except speak against the government and experience the deteriorating effect of unemployment? They could not perform actions in Washington that showed what they wanted. The campaign lacked salt.

There was an obvious need for poor people in India to use salt and there was an obvious difficulty for them to pay taxes and get the necessary salt from the British monopolistic stores. Nevertheless, police had to interfere with the very process of making salt because it violated a law. The campaign was arranged in such a way that violence against the campaigners struck them at the moment of realizing, of anticipating, the kind of social relations envisaged only in a nonviolent society. The opponent had to try to destroy this very relation, attacking even the making of a small pinch of salt for personal consumption.

Let us contrast this action with a later development of the salt *satyāgraha* that did not have this positive, goal-revealing nature.

In the beginning of May 1930, Gandhi prepared a notice to the Viceroy:

God willing it is my intention on . . . to set out for Dharasana . . . and demand possession of the salt works. The public have been told that Dharasana is a private property. This is mere camouflage. It is as effectively under government control as the Viceroy's House. Not a pinch of salt can be removed without the previous sanction of the authorities.

It is possible for you to prevent this raid, as it has been playfully and mischievously called, in three ways: by removing the salt tax; by arresting me and

NONVIOLENCE AND THE “NEW VIOLENCE”

my party unless the country can, as I hope it will, replace every one taken away;
by sheer goondaism, unless every head broken is replaced, as I hope it will.

(Tendulkar 1951–54, vol. 3: 36)

Gandhi does not tell in whose name he would demand possession of the salt works or from whom he could expect to get a concession at the site of the salt works.

Gandhi was arrested, and leadership was transferred, first to Mr. Abbas Tyabji, then to Mrs. Sarojini Naidu. Let us quote from the narrative by Tendulkar, one of the most careful writers on the subject:

On May 21st over 2,000 volunteers led by her [Mrs. Naidu] and Imam Saheb raided Dharasana salt depot, about 150 miles north to Bombay. Mrs. Naidu led the volunteers in prayer and addressed them briefly: “Gandhiji’s body is in jail, but his soul is with you. India’s prestige is now in your hands. You must not resist, you must not even raise a hand to ward off blows.” With Manilal, Gandhi’s son, in the forefront, the throng moved forward towards the salt pans, which were now surrounded by four hundred Surat Police with half a dozen British officials in command. The police carried big lathis, five-foot clubs tipped with steel. Inside the stockade twenty-five riflemen stood ready.

(Ibid., p. 40)

We all know how things developed. There was bloodshed on a large scale. An American journalist named Miller, who visited a temporary hospital, counted 320 injured, many still insensible with fractured skulls, and others writhing in agony from kicks in the testicles and stomach. The same journalist has an interesting piece of commentary from the battlefield itself:

Group after group walked forward, sat down, and submitted to being beaten into insensibility without raising an arm to put off the blows. Finally the policemen became enraged by the non-resistance, sharing, I suppose, the helpless rage I had felt at the demonstrators for not fighting back. They commenced savagely kicking the seated men in the abdomen and testicles. The injured men writhed and squealed in agony, which seemed to inflame the fury of the police, and the crowd almost broke away from their leaders.

(Ibid., pp. 40–41)

Before I comment on this, it should be mentioned that already in April a “large quantity of contraband salt was forcibly seized”; “later a large quantity was sold or distributed in the village of Dandi” (ibid., p. 32). Later, salt

was carried away—in Wadala, “sackfuls”; in Karnatak, “thousands of mounds of salt” (ibid., p. 41). One must presume that the briefing of the police before the clash with the raiders at Dharasana included a justified prediction that they would take away salt.

Now, if there is any situation in which policemen feel completely justified in stopping people with forcible means, it is where they are trying to steal private or public property. When salt is forcibly seized, policemen tend to believe it is stolen, and they act accordingly if not convinced by outsiders that what is going on is not theft.

The policemen at Dharasana must have looked on the campaigners as raiders, as private citizens trying to get hold of large quantities of salt. It is quite a different thing to try to stop people from making their own small quantity of salt out of seawater or to demonstrate for the right to do so.

Our conclusion is therefore that the preliminaries before taking up direct action were not taken care of in the salt raids of May and June 1930. The campaigners provoked and invited violence from their opponents (cf. *N*₈, p. 74).

When the police find themselves justified in brutal beatings, and their opponents do not stop their direct action, the effect may well be as the journalist Miller described it: the police become more enraged and lose control over themselves. This effect is the opposite of that intended by *satyāgraha*. The opponent must not be made to debase himself, to lose face. And one must renounce the propaganda value of displaying police and others who have lost control over themselves or are committing atrocities.

The salt raids were inconsistent with the *satyāgraha* norms in several respects: on meeting the opponent, in this case the guardians of the salt depots, there was no sustained effort to communicate with them. If it is argued that the real opponent was the viceroy and other high officials, a distinction then becomes highly relevant—between direct and indirect, near and remote opponents. Gandhi worked by personal contact, and during a direct action, it is always the near, not the remote, opponent who is to be met and persuaded.

The leader, Mrs. Naidu, asserted, as if it were already a fact, that the campaigners would be clubbed down. Therefore, no effort to communicate could reasonably be made as part of the campaign action. Perhaps it was not practically possible? The available sources do not discuss the point.

NONVIOLENCE AND THE “NEW VIOLENCE”

Further, it may be argued that the objective of the action was not properly defined. What was “to take possession” to mean? What was the relation between a law forbidding the *manufacturing* of salt to an action by which possession of already manufactured salt is proclaimed?

The objective of the action was at least not justified explicitly, it seems. The characterization (used by Tendulkar, Fischer, Bondurant, and others) of the action as a raid was unbiased, but not the phrase used by Gandhi when saying that the action had been “playfully and mischievously” called a raid. There is no clear indication that the action was not properly called a raid, and raids are certainly not 100 percent pure *satyāgraha*.

The actions themselves included important features in addition to the proclaimed objective: salt was removed and transported to unknown places, sometimes in great quantities. This exemplifies a breach of N_{25} (“During a campaign, do not change its objective by making its goal wider or narrower”). Does taking possession of include transportation and distribution? It seems that if there was a plan for how to use the salt or operate the works, the opponent ought to know about it. In a future nonviolent society, distribution and use of salt will have to be regulated somehow. The raid did not picture an ideal future situation.

Are we then forced to conclude from the foregoing that the so-called salt raids in 1930 do not exemplify *satyāgraha*? Not quite. First of all, the available historical sources are incomplete. Further, there is a wide margin of uncertainty regarding what might have been done but was not done, or what was done but did not work.

Second, the confrontation of an actual campaign with a systematization containing 25 norms can reasonably only have the aim of finding out how far and in what features the campaign differs from a campaign satisfying to an ideal degree all the norms. It would be unreasonable and unjust to limit the designation *satyāgraha* to campaigns completely satisfying all the norms. In such a case, Gandhi would not have carried through a single *satyāgraha* campaign. “I know what an inadequate follower I am of myself, for I cannot live up to the convictions I stand for” (Bose 1957: viii).

Conclusion

A confrontation of the New Violence with Gandhian nonviolence reveals similarities. Some key phrases:

Conclusion

1. Extreme activism.
2. Impatience: result now!
3. Concern for self-respect and personal identity.
4. If you lack self-respect, retaliate rather than submit to insults.
5. Make plans for parallel business and institutions.
6. Suppression, exploitation, and manipulation are forms of violence.

But there are also deep divergences:

1. Short-term physical and verbal violence may reduce long-term violence.
(Rejected by Gandhi, accepted by New Violence)
2. Fight antagonisms, not antagonists.
(Accepted by Gandhi, in part rejected by New Violence)
3. Hate suppression, not suppressors.
(Accepted by Gandhi, largely rejected by New Violence)
4. There are always basic interests in common.
(Accepted by Gandhi, rejected by New Violence)
5. First destroy all that is bad, then start building.
(Rejected by Gandhi, accepted by some New Violence leaders)

The outlook for the future is in some respect encouraging from the point of view of Gandhian thinking. The T.C.B. slogan of New Violence indicates a resolve to build up parallel institutions and furnish a constructive program.

V

Comparison with Certain Other Philosophies of Conflict

Luther and Gandhi

We hope now to have given a fairly clear, if not wholly complete, picture of Gandhi's ideas and intentions in the limited area of group conflict. Let us compare them, then, with what we know of the ideas and intentions of some other men who have lent their minds to the problems of conflict. Such a comparison can do more than put the Gandhian approach in clearer perspective. It can tell us where the comparison and contrast of different views can significantly be made and where it must fail.

There are few contemporaries who would call themselves Lutherans, but Lutheran views have contributed significantly to the political ethics of some Western countries. We find Martin Luther's views on group conflict in his doctrine of the two regiments, or realms, the spiritual and the worldly. The worldly realm, which is in a sense the kingdom of evil and which exists only because there is evil in man, is the world of militarism. God has laid the world of evil beneath the sword, as men have put wild beasts in chains.

Luther's two regiments cannot be straightforwardly identified with the church and worldly power. The Swedish theologian Anders Nygren puts Luther's view in this way:

In the worldly regiment God will maintain justice and peace, and the means he uses in this regiment are power and the sword. In both the one and the other kingdom he uses men as his servants. (Nygren 1942: 99)

Princes, soldiers, and those who are subjected to imprisonment are all servants of God. Nygren goes on:

Through the gospel God rules his spiritual kingdom, forgives sins, justifies and sanctifies. But in no way has He thereby made the worldly regiment out-dated,

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

or done away with it. In its domain the worldly regiment shall rule with power and the sword. If one tries to inject the gospel into its regime, then one commits a two-fold sin, and so will be doubly punished. Primarily one corrupts the gospel; but in addition to this one harms and corrupts the world.

(Nygren 1942: 99)

The gospel is not to be used in order to eliminate militarism, for that would be to corrupt the gospel. Luther himself says:

If someone will rule this world according to the gospel and abrogate all worldly justice and the sword . . . [w]hat will he accomplish thereby? He will turn loose the wild, evil beasts from their bonds and chains.

(Ibid., p. 101)

The substance, then, of Luther's view seems to be that if one interferes with the worldly regiment, the very few good people who do live according to the gospel will be killed. In his 1527 treatise *Ob Kriegsleute auch in seligem Stande sein können* (Whether the soldier can be considered a Christian), Luther says:

Therefore God also sets the sword on high, which obeys his will, and does not want man to say or to believe that man has discovered it or invented it. For the hand which uses this sword and kills is no longer a human hand, but God's hand, and not man but God hangs, breaks on the wheel, delivers, kills, and makes war. All the work and the justice are his. [Editor's note: Naess's translation]

For our own purposes, Luther's separate points can be listed as follows. No effort is made to reduce their harshness:

1. War and other forms of organized physical violence will and must continue indefinitely. To try to eliminate these evils is to interfere with God's rule.
2. Political life will remain essentially the same. Defense against autocracy is therefore in vain.
3. Treatment of lawbreakers will and must continue as it was in the 1500s. "Good men," as he says, must be protected against "wild animals" by any means.
4. Even if administrative institutions in a state cannot be wholly identified with God's worldly kingdom, their connection with God is nonetheless so close that any change in the institutions is tantamount

to a change in God's own regime. Thoroughgoing reforms must therefore be interpreted as rebellion against God. It is the duty of every ordinary person to obey the ruling powers. But there are, according to Luther, certain interesting exceptions. A tiny minority has the right to disobey the ruling classes. In order to have that right, one must be a so-called *Wundermensch* (miracle man), that is, one must have a special commission from God to go against worldly power. Such commissions Luther considered to be very rare. But he thought of himself as one such *Wundermensch* when he nailed his theses to the church door.

5. Luther divided men, as we have said, into the good and the evil and did not count on the possibility of the good exerting any decisive influence on the evil. The good men, the real Christians, were, according to Luther, few in number, perhaps no more than one in a thousand.
6. Evil men will not flinch from exterminating the good men if the worldly regiment did not use the sword to protect them. Luther compared evil men to wolves who would devour the sheep if the sheep were not protected. This situation would be especially serious if there were a thousand wolves to each sheep! It is no more than reasonable under such circumstances to sanction any imaginable means of defense, especially since the use of brutal means by good men does not, according to Luther, make these men any less good.
7. God sees to it that princes and other men in power are more or less morally superior to the masses. Those who have become rulers may be assumed to have certain powers that their subjects lack. There are exceptions, however.
8. There are two moralities, individual morality and the morality of rulers, or, rather, common morality and superior morality. "Thou shalt not kill" holds for the commonalty, but not for the ruling order. At times, however, the commonalty may kill: "Thou shalt not kill" and "Thou shalt not torture" need not hold for them either; as servants of the ruling order, they do have the right and often the duty to kill, but never on their own initiative.
9. The morality of the ruling order follows the "law of justice," that of the subject follows the "law of love." This is not the case, however, in situations in which commoners carry out the wishes of the ruling

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

order. In such cases, in war, for example, to follow the law of love would be to rebel against God.

Much of the harshness of Luther's teaching is thought to be inseparable from the spirit of his age. It has therefore been considered unjust to compare him to such a man as Gandhi, who lived in an age that had more or less rejected the idea of the innate goodness of the ruling classes. Let us remember, however, that there are still people today who support Luther's teaching, accepting even its harshest features. There is therefore more than academic interest in a comparison between Gandhi and Luther. It should also be remembered that some people at the time of Luther courageously condemned the cruelty and fanaticism of his teaching. Erasmus is an example.

Gandhi and Luther both criticized the political and personal conduct of their age. But Gandhi thought it not only possible, but desirable, to effect radical changes, and should such changes require the elimination of certain institutions, so much the worse, he felt, for those institutions. Institutions themselves were, for Gandhi, far from divine. War and the threat of war, for instance, were bad institutions. The structure of society needed to be changed, but it was not necessary to be a superman or a *Wundermensch* in order to oppose ruling authority.

Gandhi wanted revolution, but not violence. He saw how Hinduism had become decadent, and he wanted to purify it. Until late in his life, he considered that the original caste system (with only four castes, each having equal status) had a valuable core, but that it had grown corrupt over the centuries. Such an institution was not to be eliminated, but restored. Toward the end of his life, he proclaimed that "caste must go root and branch."¹ In short, even if there is much evil in the world, even if human institutions are never perfect, passivity in the face of evil is, according to Gandhi, altogether unjustifiable. For Luther, matters stood quite differently. No existing institution could, in principle, be bad, for God had created it. Although those who supported such an institution could be evil, as when a ruler conducted an evil war, the repetition of this evil could, according to Luther, only be avoided by the ruler's being converted and becoming a true Christian. If a Christian were to start not only good wars, but also an evil war, he would no longer be a true Christian. Evildoers may be done away with, but not institutions and their representatives.

Whereas Luther thought that since the office a man held was inviolable and that the tenure of that office afforded such a man the personal rights of respect and nonviolation, Gandhi felt it was the opponent's person (and not just his body) that was inviolable and that his acts as a representative of a ruling order were something that could be systematically opposed. Gandhi respected persons, not systems; Luther respected systems, not persons. In Gandhi's anti-British campaign, for instance, the Prince of Wales was boycotted as a representative of the ruling order, but as a man and an individual he had to be accorded every respect; neither he nor the opponents of the boycott were to suffer any injury.

Gandhi felt not only that maltreatment and torture must cease, but also that imprisonment must be abolished altogether. No distinction, said Gandhi, should be made between the law of justice and the law of love. There exists only one morality, the morality of love, and according to this morality, all people, commoners and rulers alike, stand on the same level.

Furthermore, from a moral point of view, no man can act for another man: if the hangman is to justify himself, he must do so only within his own personal morality; his role or function provides him with no excuses or justification. The basis of Gandhi's teaching in connection with group conflict is that men, wherever they have dealings with one another, must meet and interact as individual persons, not as representatives, functionaries, or underlings (see *N_{4b}*, p. 65). Every man is more than the sum of his functions, and what he cannot excuse or justify in terms of his totality is not to be excused or justified in terms of those functions.

In the systematizing of Gandhi's norms of conflict behavior it is unnecessary to introduce the highly controversial and philosophically difficult distinction between moral norms and norms that it would be ethically or strategically bad but not morally bad to break. Similarly, it is not necessary to specify whether on given occasions the verdicts bad and good are moral judgments or not. When used without specification, good and bad relate to the goals articulated in the systematization. Something is good if conducive to the realization of those goals. This is a test or criterion, not a definition.

The above paragraph is a preliminary to what follows. We are going to use the terms *good* and *bad* rather freely! All men are susceptible to influence, but not, indeed, to influence by just anyone. The more a man has developed, the greater the possibilities of his being susceptible to a good

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

influence. Gandhi's view is usually summed up as perfectionism (better, perfectibilism) or meliorism. Man can always change: "[H]owever debased or fallen he may be, [he] has in him the capacity of rising to the greatest height ever attained by any human being" (*Young India* 9.5.1929; quoted in Gandhi 1949b: 56).

Furthermore, an action may be good or bad; not so a man. If we talk about good and bad persons, our statements must be understood in reference to the actions and attitudes of persons, not to the persons themselves. A man may behave like a lamb or like a wolf, but this makes him neither a good nor a bad man. Luther thinks otherwise, and here he perhaps has most moralists on his side.

The point is essential to Gandhi's *satyāgraha*, for that way of trying to solve conflicts would certainly be a tragically vain one if one did not believe that one's opponent could be influenced by appeals to head and heart.

Luther wanted above all to bring himself into agreement with the Bible and was a member of a powerful biblical tradition of pessimism about the world and earthly existence.

In this connection, Albert Schweitzer's interpretation of Christianity is highly relevant. Johan Hygen states that as far as his views on the New Testament are concerned, Schweitzer represents the "consistent eschatology":

The religion of Jesus, according to Schweitzer, is not a religion which wishes to remake the world, but a religion which lives in expectation of the world's end. Its view of the world is pessimistic. Along with this interpretation of the earliest Christianity, Schweitzer maintains that the increasing dominance of the optimistic element came in at the Renaissance as a result of our somewhat changed attitude to the Christianity of the first centuries. It was a structural change. Indeed Schweitzer goes so far as to say that in exchanging optimism for pessimism Christianity lost its original essence. (Hygen 1954: 59)

Since early Christians expected the end of the world to come any day, there was little reason for them, downtrodden as they were, to try to change the Roman Empire and its institutions. They might attempt to convert an occasional member of the ruling order, but what would be the point in trying to change institutions just as the world was coming to an end? If one believes, however, that the end of the world is some way off, one's interest in institutions and the possibility of putting them to rights may grow considerably. Luther, on the other hand, in trying to retrace the progress of his

church back to early Christianity, unquestioningly took over the traditional view of the imminent end of the world.

We referred above to some of the tacit assumptions in Luther's teaching — assumptions about the immutability of the worldly regime, among other things. If Luther's social ideas are to provide us with any guidance today, we must believe that Luther made use of these assumptions about the worldly regime quite consciously. On the other hand, we may well doubt that he went at all deeply into worldly or social questions. His main wish, after all, was to be a guide to his own age, and we do him an injustice if we see him as trying to provide basic truths of sociology.

Most theologians recognize the uncertainty of determining what Luther's views would be if he lived today. For instance, there is some controversy about how to interpret the expression "just war," which Luther used to designate wars that he approved. A just war has been traditionally interpreted as one that is declared by a country's legal government, but this interpretation is now looked on as being as much a product of his age as was the Augsburg Confession. We cannot argue, that is, that Luther's views would imply his advocacy of just warfare today. The question of his position in contemporary controversy in this respect is still, and must remain, an open one.

According to their interpretations of Luther and of the evangelic Lutheran faith, most Lutheran theologians have felt that both the man and the faith are at a very great distance from Gandhian political morality. Nevertheless, there has always been among Lutherans a current of nonviolence. There is a widespread feeling that attitudes have changed a good deal since Luther's day, and some tend to think that the sixteenth article of the Augsburg Confession provides an adequate basis for Gandhian-like decisions on matters of politics. The words of the Lutheran creed can be given a meaning that includes sympathy with Gandhi's political morality; but they can also be given an interpretation that includes sympathy with a diametrically opposed morality.

Among dignitaries of Christian churches today, the most ardent adversaries of nonviolence are perhaps those who do not concentrate on how to make men obey the law of Christ, but on how to deal realistically with groups considered to be the most disobedient. According to Reinhold Niebuhr:

[There] is not the slightest support in Scripture for this doctrine of nonviolence. . . . It is rather remarkable that so many modern Christians should be-

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

lieve that Christianity is primarily a “challenge” to man to obey the law of Christ, whereas it is, as a matter of fact, a religion which deals realistically with the problem presented by the violation of this law.

(Davis and Good 1960: 140, 148)

Reinhold Niebuhr, like Luther, sees the camp of good people surrounded by hordes of bad and stresses a need for military “defence” against the bad (*ibid.*, pp. 300–302). In Gandhi’s thinking, on the other hand—his identification with hooligans, criminals, and even foreign aggressors—prevents him from seeing the world in black and white. It also makes him eager to meet the “bad” people—the murderers, fanatics, and exploiters—in his search for a way out of devastating conflicts.

Nietzsche and Gandhi

It is a simple matter to set Friedrich Nietzsche and Mohandas Gandhi in opposition to one another; in fact, one may think it too easy to be interesting. Nietzsche’s views on war and his expressed admiration for Napoleon and other great warriors of the past offer what looks like an absolute, and therefore unrewarding, contrast with Gandhi. Furthermore, insofar as Nietzsche contributed little to political morality, directly or indirectly, it surely does no justice to the great philosopher-poet to enlist him into the ranks of political philosophers. Nevertheless, the attempt to do so has been made. It is therefore valuable to clarify those points at which Nietzsche’s views seem vulnerable to such wayward interpretations as we find, for example, in Sorel and the National Socialists, and, of course, it is at times useful to see just where comparisons cannot be made.

Consider first Nietzsche’s views on war. How are we to interpret his approval of war, violence, and cruelty? There are two traditional interpretations of Nietzsche, the external-literal and the internal-symbolic. The literalists take Nietzsche at his word: wars can, generally speaking, be good things. According to Nietzsche, however, contemporary wars, including the Franco-Prussian War, were inglorious affairs. The Prussian victory over France was no victory at all, and the Era of Bismarck was an era of “Germans made stupid”! Could the only fault of contemporary warfare be its ingloriousness? Would wars, shorn of their accidental ignobility and tricked out with a few positive characteristics, be quite all right, or even desirable?

The answer must be a firm no. Even if Nietzsche, in his conversation and diaries, had shown enthusiasm for contemporary wars and violence because they served the repression of the physically and economically weak, the validity of the external-literal interpretation of Nietzsche's works would still not be established.

Nietzsche showed little inclination to engage personally in political controversy or group struggle. It is without undue exaggeration that Marius P. Nicolas could say, "Neither directly nor by implication, neither in practice nor in theory, was Nietzsche ever concerned with politics" (Nicolas 1938: 125). Sources for studying Nietzsche's life often lend themselves to interpretation by means of individual, rather than social, psychology. This seems evident at least in the cases of the biographical studies by Elizabeth Förster-Nietzsche, A. Ahlberg, Carl Roos, and Hugh A. Reyburn. The difference in the scope and quality of the critical literature in the cases of Nietzsche and Gandhi is enormous. Compared with Gandhi, Nietzsche is almost unknown to us.

It would require too much space to launch into a detailed justification here of the internal-symbolic interpretation of terms in Nietzsche's works such as war, cruelty, and violence and to define them in terms of inner struggles or conflicts fought in the mind by those concerned with their own weakness. Suffice it to say that Nietzsche seems clearly to have conceived himself to be continually declaring and waging "wars." These could not be meant otherwise than symbolically. Of his book *Human All-Too-Human* he writes that it constituted "a hundred-fold declaration of war." He fought established Christianity with the same intensity as did Kierkegaard. "It is now that we shall need warriors," he remarked after the immense Prussian so-called victory at Sedan. These and other sayings show his preference for a martial vocabulary, which, however, omits entirely any reference to international relations. Attempts, therefore, to construct a political morality or a theory of group conflict on the basis of Nietzsche's writings would seem doomed to failure. Comparison with Gandhi at this level, then, is impossible.

But what about Nietzsche's noble warriors? Are they anything like Gandhi's *satyāgrahin*? These warriors are courageous, and honest, and they are masters of open combat. They make sacrifices, take responsibilities upon themselves, and never extol suffering. They are truth seekers, free spir-

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

its and their personal *Weltanschauung* is the arbiter of all their decisions. They neither evade issues, shun conflicts, nor flee from fearful, even deadly, consequences, but hold their ground, come what may.

Gandhi expected similar qualities of his *satyāgrahin*; in fact, he has often been criticized for the harshness and cruelty of his demands. His admiration for the proud but warlike Pathans and his criticism of the weakness of some Hindus seem to reflect an uncompromisingly strong and militant attitude.

No systematic comparison of Gandhi and Nietzsche, however, is possible even in this area. The problems involved in interpreting the two men are vastly different. Nietzsche, perhaps intentionally, never makes it clear when he is trying to convey something in a highly suggestive but not fully literal way as opposed to when he intends people to be able to point to some sentence and say, "There, that is what Nietzsche thinks about it." In other words, whereas Nietzsche talks to us through an opaque screen of inspiration, Gandhi utters the most direct statements in the simplest of prose.

Furthermore, if we can talk at all of Nietzsche's system of morality, it is clear that we can say that it lacks any account of how to proceed or what to expect in particular situations. His statements about contemporary events are confined to remarks about, inter alia, wars, Jews, the British, the French, and so forth. The generality of such references lends support to what seems the correct way of interpreting Nietzsche, a way that implies that these general statements are less straightforward references to real instances than illustrations of aspects of the great struggle man must have with himself if he is not to be destroyed. The key, it would seem, to much of Nietzsche's discussion of war in *Also sprach Zarathustra* is to be found in the statement "Your highest thought shall thou let me bid you and cry out: Man is something that shall be overcome."² The picture we are given of contemporary man is of a weak and cowardly being, passive, compromising, dishonest, evasive and foolish, a being that feels compassion but refuses to commit itself to the hazards of moral action. The man Nietzsche would conquer is a self-abnegating, un-self-realized man. Self-realization is a matter of self-conquering, insofar as the self must be overcome. This notion of annihilating the weakness of man and thereby admitting a great self that has no known bounds is perhaps the main principle that emerges from any prolonged acquaintance with the works of Nietzsche. Here Gandhi and Nietzsche agree.

For Gandhi, self-respect and self-realization require the expansion of the self. His self-lessness has as its opposite egotism and self-abnegation.

It is impossible, however, at least at the present time, to explicate any further principles in Nietzsche's philosophy that would allow us to compare the Nietzschean system with others. As for Nietzsche's connection with Gandhi, although we can say they have certain values in common, such as fearlessness, we can say little more.

Tolstoy and Gandhi

Leo Tolstoy was Gandhi's great inspiration in the latter's efforts to evolve a theory of politics that could accommodate his moral system. With regard to opposing the powers that be, Tolstoy was the more radical and uncompromising of the two. In specifying very clearly how the authorities should be approached in an actual conflict, Gandhi expressed his belief that there are times when a good cause can be supported by working together with the authorities, even though they are responsible for violence and oppression. Tolstoy's belief seems to have been, on the contrary, that a good cause can never be supported in this way. In one important respect, then, Gandhi appears to have differed from his main source of inspiration.

In his detailed accounts of the cruelties inflicted on the peasants by the czarist authorities, Tolstoy gives free rein to his indignation. There is never a hint of any possibility of future cooperation with the perpetrators of such terrible violence. He writes as though he intended to convey to his readers a mood of hatred not just for the institutions, but for all of their representatives as well.

With Gandhi, it was quite otherwise. He presents the assaults and injuries suffered by himself and his followers in such a way that we are roused more to sorrow than to hatred and to a willingness to fight the causes of animosity and distrust rather than to a desire to wreak vengeance on the offenders. Gandhi had a rare gift for the vehement condemnation of an act without condemning its agent. His unwillingness to make personal accusations extended to fanatics and terrorists since even they were to be regarded as potential fellow workers. They were truth seekers, just as he was. They were trying to influence in their direction, he in his. No one possessed the truth, everyone erred more or less, and no one could know his own error but

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

by further nonviolent struggle. In this truth seeking, no one could be written off; no one was beyond redemption.

The tone of Gandhi's writings differs from that of Tolstoy's as the mental attitude of a builder does from that of a destroyer. Romain Rolland, in his book on Gandhi, written in 1924, said with some justice:

With Gandhi everything is nature—modest, simple, pure—while all his struggles are hallowed by religious serenity, whereas with Tolstoy everything is proud revolt against pride, hatred against hatred, passion against passion. Everything in Tolstoy is violence, even his doctrine of nonviolence.

(Rolland 1924: 147)

This is vast exaggeration but it points to a central difference of posture, a difference relevant in recent years between Tolstoyan haters and destroyers of the establishment and Gandhian builders of new lifestyles.

In his "Letter to a Hindu," Tolstoy interprets the holy writings of Hinduism to be consistently of a nonviolent character.³ Of one of these scriptures, the Hindu Kural, he says:

The aim of the sinless One lies in not doing evil unto those who have done evil unto him. Even if a man causes suffering to those who hate him without any reason, he will ultimately have grief not to be overcome. (Nag 1950: 86)

But there is more than enough grief in the world, and the sinister Tolstoyan prediction of grief not to be overcome goes against the *karmayoga* function of the Gandhian approach. If he harbors a "grief not to be overcome," whatever the cause of the grief, the Gandhian *yogi* of action will work to eliminate just that grief.

Following these passages from the Kural, Tolstoy, in referring to attitudes in Russia and Europe, concludes:

The recognition that love represents the highest morality was nowhere denied or contradicted, but this truth was so interwoven with all kinds of falsehoods which distorted it, that finally nothing of it remained but words. It was taught that this highest morality was only applicable to private life—for home use, as it were, but that in public life all forms of violence—such as imprisonment, executions and wars—might be used for the protection of the majority against a minority of evil-doers, though such means were diametrically opposed to any vestige of love. (Ibid., p. 86)

Lenin praises this criticism of injustice and exploitation but condemns Tolstoy's doctrine of nonresistance and the lack of a program of action (Gandhi 1958, vol. 15: 202–09; vol. 17: 49–53).

Tolstoy paints a dark picture of the terrifying perversions into which this highest of moralities has today been transformed, but he does not call on those who still uphold such a morality to act in defense of it. In fact, in one of his letters to Gandhi, Tolstoy went so far as to say that “as soon as resistance is admitted by the side of love, love no longer exists” (Nag 1950: 72). Gandhi did not resist evil—he ignored it. Gandhi wanted to build; he wanted to evolve and test a strategy that aimed at reestablishing respect and faith in the morality of love. It was essential, moreover, that this be done with the cooperation of those responsible for the distortion. He did not resist their game but started his own. His principles invited such cooperation, a cooperation his trust in human nature allowed for as a possibility. Cooperation, and inevitably compromise, with men of authority led to Gandhi's accepting, for the time being, a number of disagreeable features in the existing institutions. This earned him the alarmed protests of the Tolstoy camp, which rejected any kind of cooperation with any state institution.

Vain protests! The program of Gandhi was to cooperate as much as possible with the leaders of institutions without committing himself to acceptance of those institutions. He cooperated with jailers but never accepted the institution of imprisonment. The Tolstoyans did not accept the distinction between man and institution. Gandhi, on the other hand, was not always able to be entirely consistent in his applications of the distinction.

In terms of his own political strategy and in contradistinction to those of Tolstoy, Gandhi was able to lay stress on the not always sinister aims of those who did violence, and he rejected, moreover, the idea that the negative value of an action increased proportionally to the intensity and extent of the violence employed in it. His attitude toward representatives of vast military organizations was therefore not, as in the case of Tolstoy, one of abhorrence. Gandhi could admire those who fought in a way they considered to be appropriate for what they deemed right; if this involved violence, then it should be remembered, said Gandhi, that such people are also more likely to be courageous enough to employ nonviolent methods than are those who habitually avoid all physical conflicts. The absence of physical violence

can be due to cowardice; its presence may be due to love. Gandhi defended lovers of a pure Hindu society who tried to kill him. They had the courage to do what others only wished. Gandhi sought, however, to lead the force of love into constructive channels wherever it had gone astray, and he was always ready to meet men to try to persuade them to relinquish their trust in violence as a method.

Unhappily, the Gandhian approach is not readily taken up by people who today feel more or less helpless in their relations to "the establishment." They are more likely to join a Tolstoyan camp of haters and pessimists, of nonresisters or of promoters of violence.

Jaspers and Gandhi

Karl Jaspers (1883–1969) is one of the few philosophers of this century who commands respect in all quarters as a sincere, intellectually honest, erudite, and versatile philosopher. Starting as a psychiatrist, he soon developed a comprehensive view of history, society, and man. Unlike some of his colleagues, he courageously stood up against Hitler's repressive bureaucracy. He was dismissed as a professor in Heidelberg in 1937 but was reinstated as director (*Rektor*) in 1945.

Jaspers's close experience of overwhelming terror left a deep imprint, and he may well count as one of the weightiest doubters regarding the outlook for nonviolent overthrow of terror regimes. But the same experience made him also a staunch believer in the necessity and feasibility of infusing something suprapolitical (*überpolitisch*), something over and beyond politics, in the aims and workings of politics: an ultimate aim, a quest for freedom, dignity, and justice to direct the day-to-day efforts of the struggling politician.

In his *The Future of Mankind*, he uses the phrase "politics as such" in the sense of rather tough *Realpolitik*, taking it as axiomatic that the aim of politics as such is power and the increase of power — without any further aim except the personal aggrandizement of the politician. Gandhi's experience in South Africa and India did not induce him to accept this rather pessimistic view of the self-realization of politicians!

A politician cannot as such possibly have anything against violence or even large-scale terror, Jaspers maintains, except out of a purely opportunis-

tic regard for rapid success. "Politics is essentially a commerce with *Gewalt*" (Jaspers 1958: 63).⁴

Now, what is *Gewalt*? Here we touch on an important ambiguity in German philosophy of history and politics. The term oscillates in its use between the fairly general one of "power" ("being able to") and the more specific one of "violence" (or "coercive, repressive capability").

When Jaspers declares that with abstinence from *Gewalt*, "politics comes to a halt," it is clear that he has a surprisingly broad concept in mind because in the following, he suggests that only in very special circumstances have very few individuals abstained from the use of *Gewalt*:

This has actually happened in the lives of the saints who followed the Word from the Sermon on the Mount: "Resist not evil; but whosoever shall smite thee on thy right cheek, turn to him the other also." Where such a life remains consistent it has its own dignity, however undignified it may be politically. It is a life that is heedless of either living or not living, a life indifferent to itself, existing because of chance and circumstance, entirely absorbed by something outside this world, to which the world does not matter.

(Jaspers 1961: 63)

The saint perpetually hiding himself in the desert not only renounces violence, but renounces his potential to exercise the power of influence. But a person making use of his full power to convince rather than coerce cannot be said to be "entirely absorbed by something outside this world." In the above quotation, Jaspers therefore has in mind a renunciation of power in an extremely wide sense, for instance, of "interaction with others." He does not answer the question "Is politics without violence but with exercise of power an absurdity?" Jaspers's reference to religionists who manifest extreme indifference toward political questions does not allow him to give a clear answer.

But let us look at the following syllogism: "Politics without *Gewalt* is an absurdity. Gandhi made politics. Therefore Gandhi realized the absurd."

Jaspers actually draws such a conclusion. Gandhi willed the impossible: politics by nonviolence (*Gewaltlosigkeit*). He had great success: the liberation of India. So the impossible is possible?

Jaspers's ultimate answer is no. Gandhi used *Gewalt*, not physical, but moral. He merely shifted from one form of *Gewalt* to another.

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

At this point, the nearest verbal equivalent of *Gewalt* is *compulsion*. According to Jaspers, Gandhi *compelled* the British to withdraw because the moral sensibility and the high moral ideals of the British made it impossible for them to resort to systematic terror against the Indians. Terror, if in sufficient doses, always succeeds politically:

Absolute rule is impossible whenever it does away with restrictions and qualms, whether in naive political action or by referring to a revealed deity. Such terror makes for submission, in which proud nations that value their freedom will perish. Nations do not react alike. (Jaspers 1961: 38)

We can no longer doubt that unlimited terror will destroy all resistance that does not consist of equal physical force. The subjection of Hungary has shown to the dullest eye that the totalitarian Russian terror would have preferred Hungary as a desert to Hungary free. Against total violence there is no help in less violence, nor in nonviolence. (Ibid., pp. 39–40)

Apart from the implausibility of the idea of a nation being destroyed without its own help, the conclusion does not follow from the premises as far as they concern the strategies of Gandhi. The premise “Gandhi made politics” is correct, but the other premise, “Politics without *Gewalt* is an absurdity,” perhaps only holds for the very wide concept of *Gewalt*, the concept of interaction with others or influencing others. Jaspers has only referred to the fact that saints in deserts cannot make politics. There we can agree!

We must therefore formulate a second syllogism: “Politics without exercise of power *in any form* is an absurdity. Gandhi made politics without using the form of power of violence and preponderantly without even the use of a subspecies of violence, coerciveness. Therefore, Gandhi realized the absurd.”

The conclusion is clearly wrong. Only if Gandhi renounced power of *any* form does the conclusion follow. Actually, Gandhi is completely clear in his acceptance of the use of power, and the translation of *satyāgraha* into “soul force” or “moral power” strikes something essential. His stress on activism, his aim to influence, is a central feature of his teaching. An increase in self-realization involves an increase in “power to,” not “power over”—an increase in ability to reach one’s goals, not an increase of domination.

Let us then go back to Jaspers’s conception of Gandhi’s relation to the empire: Gandhi used the nonpolitical moral principle of the British to

compel them to give up India. He did not resort to this act of blackmail (*Erpressung*) consciously. On the contrary, he tried to avoid compulsion and stopped a *satyāgraha* if it developed into violence. He denounced moral coercion and tried, sometimes unsuccessfully, to eliminate moral coercion from his fasting.

The success of Gandhi's method is, according to Jaspers, relative to a set of moral values: it presupposes an opponent who would rather relinquish power than transgress his own morality. Without saying as much, however, Jaspers implies that the imperial policy of Britain was suprapolitical—that goals of justice and morality intruded into it in a decisive way:

It was only under the British, and only under their attempt at liberal rule which is unique in the history of empires, that Gandhi could succeed. Never before would such nonviolent policies have led to the same outcome, and in the future they could lead to it only under conditions analogous to British liberalism, freedom of speech, and legality. The liberation of India is far more a matter of British politics, far more the consequence of England's struggle with herself, than it is an Indian feat. (Ibid., p. 38)

Before critically discussing this point of view, we shall continue our presentation of Jaspers's view.

Extreme terror can only be met and conquered by violence (*Gewalt*). Whatever the outcome, the violent resistance against terror has a value in itself. It exemplifies the kind of sacrifice human beings must continue to perform in order to remain human. Life is not worth living when the eventual sacrifice of it is not accepted.

But bound up with the sacrifice is something timeless, hypersensory, and unconditional. Even if "useless," it is not "senseless." (Ibid., p. 43)

A lasting peace could only be achieved if the greatness, the strength, and the valor of the sacrifice hitherto shown in history by the soldier would now materialize in no lesser form. (Ibid., p. 56)

The responsible politician in an extreme situation must, according to Jaspers, use violence and order the soldier to kill. However, he cannot wholeheartedly will this killing because "thou shalt not kill," and he cannot accept the convenient distinction between private and state morals. He must,

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

as “ethician of responsibility” (*Verantwortungsethiker*) remain permanently in a state of immense (*ungebeuer*) strain.

Jaspers here lets his eminent compatriot Max Weber speak:

So Max Weber asks, ‘What kind of man must one be to put one’s hand in the spokes of the wheel of history?’ And he sees it as immensely moving when someone who feels responsible for the consequences—directly and wholeheartedly—at some point says: I cannot do otherwise, here I stand. For this situation must sooner or later confront all of us who are not dead inside.⁵

(Jaspers 1958: 77)

The limited aim of our comparison compels us to make a stop here. The question must be answered, How do Jaspers’s views (1) of Gandhi and Gandhi’s campaigns and (2) of *satyāgraha* compare with the views presented in the previous chapters?

It seems that for Jaspers, Gandhi’s political activity consisted only of fighting for the political independence of India and that one of his decisive weapons was that of coercive fasting. This is surely a one-sided view. In our presentation, we have stressed the other politically relevant campaigns in South Africa and elsewhere. Gandhi saw no ultimate aim in political independence from Britain, and only a fraction of his work was devoted to that end. Most of his *satyāgraha* was devoted to internal politics. On the day of independence, August 15, 1947, he, of all leaders, refused to deliver any public message. He fasted and prayed. His more important goals were as far away as ever.

It is generally doubted that Gandhi used fasting consistently in accordance with the norms of nonviolence, and Gandhi himself is one of the doubters. In certain cases, his fasting was a threat. His 1947 fast in Calcutta was of a terrible kind insofar as he pressed his followers to make the leaders of the riots sincerely promise not to continue rioting. Without this pressure, his followers would presumably not have tried so desperately to convince the rioters of the futility of rioting. Without the threat of fasting to death, rioting might have continued in East Bengal. There is, of course, no theoretical reason to believe that *only* a fast by Gandhi at that time could have elicited such a great effort to find and persuade the rioters. In this case, as in most others, we are not warranted in concluding that no other kind of action on the part of Gandhi—and Gandhi mastered a great number of different kinds of direct action—could have

brought about the same result or, even more absurdly, that nonviolence in general, apart from the very special activity of Gandhi, cannot dispense with coercive fasting.

The picture of Gandhi's activity as something that sometimes had to become coercive cannot be upheld if a more detailed account is given of the various campaigns he led during the fifty years of his struggle.

Fasting is then seen to be a minor issue. Even if the picture drawn by Jaspers is left unchallenged, the consequences for an appraisal of nonviolence as presented by norms, hypotheses, and non-Gandhian campaigns remain to be explored. After all, Gandhi erred and was sometimes led astray, as he himself conceded.

Jaspers refers in his bibliography to only two writings on Gandhi, that of the saintly Andrews (Gandhi 1930) and the learned and painstaking work of W. E. Mühlmann (1950). Andrews is highly idealistic and unworldly when considering Gandhi's relevance for fighting totalitarian terrorism, and Mühlmann is deplorably dependent on German conceptual frameworks, as is shown in the last chapter of his book, where it appears as if he suddenly forgets what he has painstakingly described in his first chapters. We may perhaps be permitted to suggest that Jaspers might have acquired a still more favorable picture of Gandhi's activity—and perhaps a somewhat less idealistic picture of the British policy of repression—if he had used British and Indian sources more extensively. One thing that Jaspers could have taken profitably from Mühlmann is the latter's translation of *himśā* to *Violenz*, a rather awkward term in German, but nevertheless a much better translation than *Gewalt*. With *Violenz*, it is difficult to maintain that politics is in its essence a commerce. The use of this term also makes meaningful and important the question of to what degree a politician can dispense with *Violenz*—that is, organized physical violence. This is clearly a different issue from the strange question of to what degree a politician can dispense with power.

When the nonviolent leader more or less *compels* an opponent to listen, using the Socratic way of not leaving anybody at peace, he still does not compel the opponent to believe in what he has to say. If the opponent, after listening (more or less against his will), arrives at the conclusion that there is, after all, some reason and justice in what is said, he does not take the act of persuasion to be an act of coercion. If I am genuinely persuaded about something, if reason or justice motivate the change in belief, the influences

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

leading up to my change of opinion are not, and should of course not be, classed as coercive. My change of attitude is in that case my change, proceeding from my thinking and feeling. If the opponent appeals to my ethical convictions and makes use of them in order to inspire me to change my attitudes in a crisis, this is not an encroachment on my sovereign freedom. My power (*potentia*) resides in my ability to act out of my own individuality, spontaneously and without compulsion from the persuader. My power is not that of resisting or shutting out impulses from the outside, but of choosing how to act on them. My freedom is here that of choosing with my total personality on the basis of evidence.

Gandhi admits there are momentary situations of nonviolent powerlessness, that is, in which persons confronted with a situation require a level of nonviolent power and ability that at the time they do not possess. It is then right for a person to use physical violence or other kinds of violence in order to defend what it is his deepest responsibility to defend. However, Gandhi condemns the organization and planning of future situations of helplessness. You are not allowed to declare yourself or your nation helpless next year. I think this can be generalized to all who adhere to nonviolence in group struggle. Jaspers stresses that at a given moment, there is in the world a capacity of total terror, of the complete annihilation of peoples, that if released, nonviolence could not stop. However, if we follow the injunction to seek the center of conflicts, there is, in Gandhi's view, no place for passivity until mechanized divisions cross the border, and there is no place for armament. The situation calls for training in nonviolence, not declarations of future nonviolent powerlessness.

It is scarcely controversial that the rise of Hitler and the deportation of Jews were only possible because of widespread passivity. In facing the future, there are threats of terror and organized violence from many quarters. These threats must be resisted immediately. It is during armistice, conventionally called "peace," that campaigns of nonviolence have the best chance of winning. The predominant military outlook teaches, however, that supreme sacrifice and patriotism are things that are only called for in war, not in the shorter or longer periods between wars. Jaspers directs his attention toward the sacrifice of soldiers in war but does not study similar sacrifice during so-called peace. He does not consider the possibility of creating brigades of nonviolence and other institutions that call for sacrifice between wars.

When it comes to theoretical, ultimate conclusions, there is nevertheless a great similarity of outlook between Jaspers and Gandhi.

Jaspers works with a notion of a “responsible statesman” who has goals identical to those envisaged in the metaphysics of Gandhi and who in his dealings with the opponent follows nearly identical maxims (Jaspers 1961: 326 ff.). (Such a statesman is a politician in Gandhi’s terminology, but not in that of Jaspers.) When facing totalitarian dictators, the responsible statesman will communicate as Gandhi would have tried:

The statesman will address the totalitarians without replying in kind. He will not return lie for lie, abuse for abuse; rather, his very word will be truthful. He will speak calmly and simply. His words and questions and statements will unmask falsehood without having to call it false in so many words. Thus he will reach the souls of the totalitarian leaders; at first, he may well be the man they hate the most. But he will go on patiently, ceaselessly, and on the strength of an attitude that hides no mental reservations, he will not only open the eyes of more and more free peoples but will get through to the subjects of total rule. It is difficult to speak like this, not once but all the time, and to make such language ring as the irresistible voice of the world. Today we hear it on occasion, like a miraculous note that touches us and quickly fades away; it is anything but the common tongue of politicians in free countries. But if it is to grip men as the harbinger of truth, it must be heard every day.

(Jaspers 1961: 245)

Here we see expressed the norm of maximal, persistent verbal communication and the belief in the unlimited power of truth to reveal both itself and untruth (Spinoza). But acts count more, and when Jaspers lets the responsible statesman take part in the armaments race, this activity communicates a formidable threat. If the responsible statesman is quite sincere when opening negotiations, he will have to include something like the following admission: “Since I am now trying to be completely truthful, open, and sincere, it is my duty to mention that if our present negotiations should take a tragic turn, there will come a moment after which I shall have to try to deceive you as best I can. Unhappily, I cannot at that moment tell you that the period of truthfulness is over, as this would defeat my effort to deceive you. It is, however, my sincere hope that such a moment will not come.”

According to the tenets of nonviolence, only very limited trust can be expected when there is a threat of violence behind the proposals made. “If our extremely modest and reasonable demands are not met, then . . .” Are

COMPARISON WITH CERTAIN OTHER PHILOSOPHIES OF CONFLICT

they really modest? Who is the judge? Behind the policy of nonviolence, there is a hypothesis of fallibility, an uncertainty regarding the reasonableness and justice of one's own claims and one's own analysis of the conflict situation.

The statesman, as conceived by Jaspers, cannot stand naked before the opponent as the leader of nonviolent struggles is supposed to do. With one hand, the "responsible statesman" grasps the hand of his opponent, but the other has a firm hold of the telephone linking him to the headquarters of psychological and physical violence, "keeping the powder dry."

One cannot have it both ways: penetrating the soul of a tough opponent by one's utmost sincerity and taking no undue risks should he not be properly impressed. There is no indication, however, that Jaspers does not see the perils of his own position or that he underestimates the difficulties of giving a reasonable, clear account of how to react to powerful terror regimes and to the existence of atomic weapons. The above abstracts do not do complete justice to his thinking. His main effort is to underline that mankind is at a turning point: either the more-than-political aims must penetrate politics or we shall all perish. Having this in mind, he is in no doubt as to where to place Gandhi:

Today we face the question of how to escape from physical force, and from war, lest we all perish by the atom bomb. Gandhi, in word and deed, gives the true answer: Only a superpolitical force can bring political salvation.

Series Editor's Introduction

Arne Naess — A Wandering Wonderer: Bringing the Search for Wisdom Back to Life

[The pre-Socratics'] attitude, in the main, was genuinely scientific whenever it did not merely embody the prejudices of their age. But it was not *only* scientific; it was imaginative and vigorous and filled with the delight of adventure. They were interested in everything—meteors and eclipses, fishes and whirlwinds, religion and morality; with a penetrating intellect they combined the zest of children.

From this point onwards, there are first certain seeds of decay, in spite of previously unmatched achievement, and then a gradual decadence. What is amiss, even in the best philosophy after Democritus, is an undue emphasis on man as compared with the universe.

Bertrand Russell, *History of Western Philosophy*

When the full scope of Arne Naess's philosophical contribution is examined carefully and placed in context, it will very likely be viewed as one of the twentieth century's most significant and enduring.¹ Naess has made bold and innovative contributions to conventional academic philosophy and social research, particularly in the areas of behaviorist epistemology, empirical semantics and communication theory, scepticism, scientific and cultural pluralism, Gandhi and Spinoza scholarship, normative systems theory (as a general approach for exploring premise-conclusion relations), and the very idea and relevance of total systems (total views in Naess's *lingua*). Perhaps even more significant—although one should not view it as distinct or decoupled—has been his commitment to reconnect philosophy to life experience. This effort is similar to Bertrand Russell's in that it has been particularly pronounced in later life. Naess, however, carries this com-

SERIES EDITOR'S INTRODUCTION

mitment to expand philosophy's sphere of concern to life in general and the Earth. Essential to this endeavor, is the mature Naess's radical initiative to reconceptualize reason expansively, to integrate reason with emotions and feelings *in practice*. In some cases this includes using mythopoetics to make a case or communicate a point.² What makes Naess so special is that even while paddling against the current, he exhibits tremendous optimism and openness, joy, and a disarming, infectious playfulness.

Naess strives to *live his philosophy*. For more than thirty years, he has sought to reshape the philosophical debate by drawing from and building on his previous work to outline a nondualistic, nonanthropocentric philosophy of life that affirms the ultimate unity and interdependence of all living beings, while maintaining their individuality. His philosophy celebrates the Earth's richness and diversity—both cultural and biological. That said, one of the main purposes of the *Selected Works of Arne Naess* (SWAN), however, is to provide you, the reader, with the resources to make your own informed judgment regarding the significance of Naess's philosophical legacy.

At age ninety-two, Arne Naess has lived a long life filled with wonder. In his words, he has “seen life”—traveling the world, spending significant periods of time on every continent. He has experienced the world somatically and intellectually in concert as one mind-body—as a being—and seen more than most of us can imagine.

When Naess was born, Archduke Francis Ferdinand was alive, automobiles were in their infancy, and most homes did not have running water. Home refrigerators had just begun to be produced. Television and computers were only imagined. Only a few years before, after being contemplated for millennia, the first controlled and sustained powered flight took place, ushering in a period of ever-accelerating transfer of materials and information, but not necessarily a commensurate increase in knowledge or wisdom.

Consider that Naess has lived through two world wars (and too many “limited” conflicts to count), the rise and fall of the Soviet Union and East Germany, the “liberation” of India and Pakistan, the onset of climate change, and the hastening of “global terrorism.” He has been the beneficiary of tremendous medical advances and unprecedented economic growth, and he has seen the ravages caused by escalating consumption, globalization, and disparities in both income distribution and access to resources. He is part and product of humanity's largest growth spurt. And he has witnessed the most significant loss of cultural diversity and the onset of

what may become the planet's greatest extinction crisis—but is surely the greatest extinction crisis ever caused by one of Earth's own species. Naess has also seen and, at times, participated in the many hopeful responses to these ills—the peace, social justice, and ecology movements; nonviolent actions to support antiglobalization efforts and protest dam building; voluntary simplicity; conservation biology; wildlands philanthropy; bio-regionalism; green business and architecture; ecological design, economics, engineering, and restoration; and sustainable agriculture, forestry, and fisheries management.

Everyone is influenced by the times and events of his or her day. The “prejudices of our age” filter into our lives and work more or less consciously and actively, but at a minimum they enter passively. What is the mature Naess's approach to philosophy, how is it a uniquely self-aware and responsive product of his day, and why should it be seen as monumental?

Naess likes to see himself as a “philosopher of life.” The thought of simply being an academic philosopher—living a life of the mind—makes him restless and uneasy. For Naess, “wonder” is both the point of departure for philosophy and the focus of the enterprise. He is the philosophical equivalent of a hunter-gatherer using his wits and intuition to seek out food (for thought) in a fecund landscape. As they were for the ancient Greeks, science and philosophy are inextricably intertwined for Naess. Science, as the application of reason through empirical investigation, cannot be separated from rational reflection on the nature of reason, and vice versa. For the mature Naess, though, philosophy and science are also distinct. Philosophy is the unique realm in which we take up the deepest, most profound, and most fundamental problems. From Naess's vantage, which defines philosophy openly and discursively, the questions that have fascinated and plagued people for millennia have not changed much and they are not likely to change significantly in the future.

Naess's view of philosophy includes the traditional epistemological question “What can we know?” and the ontological question “What main kinds of things are there?” But it also includes “How do we measure?” and “How do we know?” as well as “What is the relationship between the knower and the known?”³ These are questions that are likely to vary with cultural and social circumstances, but this does not, for Naess, imply cultural relativism. By its nature, this view of philosophy runs counter to the dream of the logical empiricists; it cannot be restricted to investigations of

SERIES EDITOR'S INTRODUCTION

“fact” or “logic.” It is imbued with fundamental valuations. Being a philosopher, for Naess, is thus a deeply personal and intimate matter that requires us to engage all of our powers and experience. It should also include questions such as “What are your aims in life?” and “What’s driving you?” as well as encourage a practice of deep and open argumentation by asking repeatedly, “Why do you hold that *p*?” in order to unearth underlying premises and hypotheses. For Naess, all these questions have an empirical component. He sees it as a duty for a philosopher to extend research into the creation and use of empirical methods to address these aspects, unless these questions can be adequately addressed by an existing empirical science, in which case it is fine for a philosopher to perform research here, but it no longer constitutes a *duty*.

In Naess’s view, philosophy is ultimately concerned with how *we*, through our experiences, perceive the world, the world’s relation to ourselves, and the basic features of the condition of people. It is the realm in which we pose sophisticated questions to address perennial problems, probe them from different angles (in Naess’s case, from as many angles as possible), and test and apply the insights to real life—to what we do and decide every day. Its purpose is not to arrive at definitive answers. The purpose of philosophy, rather, is to help us understand what *we* believe in from our innermost perspective, expand this perspective continually, and facilitate communication—so that we might contribute toward improving the state of affairs of the world.

While initially attracted to Bergson’s *les données immédiates de la conscience* (the immediate data of consciousness), Naess grew disenchanted when he recognized that one becomes lodged in an endless circular loop and never exits consciousness. Naess clearly believes that the unexamined life is not worth living (his life is a testament to Socrates’ edict), but he appreciates that disembodied, introspective examination comes at great peril. A mind-centered focus on “examination”—where subjects exist separately from objects, theory is isolated from praxis, and knowledge is decoupled from wisdom—very quickly degenerates into meaninglessness. Worse yet, separating people from and raising people above nature and the coevolutionary process that created us—and provides for our sustenance—can be inimical to life and the evolutionary process.

Nature, that which is, the reality of the pre-Socratics, is Naess’s philosophical palette, not the “world” of his own consciousness as has become

the norm with so many contemporary philosophers since Descartes. Popper and others posit the existence of three worlds that correspond to the development of our commonsense view of reality. World I is the physical world, the "external world," the world of our sensory impressions. World II is the world of all conscious experience, the psychological world of the "immediately given," which incorporates our feelings and intentions. World III emphasizes the logical content of reality. Naess finds these multiple views of reality unconvincing and potentially dangerous. With a worldview inspired by Spinoza's *Ethics*, he is fundamentally opposed to the notion of multiple worlds.

Naess's mature philosophical approach and contributions are shaped by full engagement with a relational reality, in which no firm subject/object, substance/property, universal/particular, fact/value dualities exist. John Muir's famous, deceptively simple aphorism sets the stage: "When we try to pick out anything by itself, we find it hitched to everything else in the universe." Reality as we experience it, according to Naess, is a dynamic, multilayered manifold of hierarchically related gestalts—of which we are always a part. It is the opposite of atomism. Contrary to the dominant, Western way of viewing reality, there are no extrinsically connected discrete objects or "things in themselves" in the sense of Kant's *Ding an sich*. With Naess's "gestalt ontology," there is no dualistic "I" standing outside of reality looking in. Living beings, individuals in the sense of Spinoza's modes, are spatiotemporal manifestations of "one substance," nature or reality. As Naess points out in *Freedom, Emotion, and Self-Subsistence* (SWAN VI), Spinoza's medieval terminology of substance, mode, attribute, God, and Nature is dispensable. In addition, Naess goes on to characterize "living beings" broadly to include individual organisms as well as ecosystems, rivers, mountains, and possibly Earth (Gaia).

Naess's view of reality calls for a gestalt shift. His gestalt ontology does not stop with gestalt psychology's simple notion of holism, where the whole is more than the sum of the parts. It goes on to add that the internally related subordinate gestalts are themselves more than mere parts. There are no parts as parts or wholes as wholes; higher-order wholes are not reducible to lower-order wholes. The concrete contents of reality have gestalt character. For Naess, we experience reality spontaneously and our experience of the world is made up of gestalts. "[This] is the world we experience. Nothing is more real."⁴ People create abstract structures to reflect

SERIES EDITOR'S INTRODUCTION

on or analyze spontaneous experiences and their structure; they are the interrelations between spontaneous experiences. Mind and body are mental contrivances and conveniences—abstract structures in Naess's parlance—for helping us to describe, model, or understand certain states of affairs. They are not the contents of reality. Only individual occurrences of spontaneous experience make up the concrete contents of reality.

What are the consequences of Naess's "ontological realism" as expressed in the form of gestalt ontology? First, living organisms have different levels of access to reality, based on their capacities, experiences, and backgrounds. This implication of "reality is one" plays a central role in the mature Naess's approach to philosophy of science. One of his main thrusts is to undermine the claim that the exact physical sciences show all that is, that they have a privileged view of reality. In his view, science creates extremely abstract structures of what is real, but those structures do not actually *describe* any of reality's concrete contents (descriptions are themselves normative). Jakob von Uexküll, the famous ethologist of the early twentieth century, whom Naess read closely in his youth, helps clarify this notion. "As the spider spins its threads, every subject spins his relations to certain characteristics of the things around him, and weaves them into a firm web which carries his existence."⁵

Different people experience reality differently, yet we often, incorrectly, speak of *different realities* as if they existed. By the same token, identical accounts of reality in no way imply verification of that view by correspondence; from Naess's perspective, such accounts by themselves are merely a sign of cultural poverty. "God" could have created the Earth and life 6,000 years ago, but the evidence to support this case is thin and the evidence to support evolution is stronger, in part because biological science and paleontology generally employ a greater level of depth of intention and thus aspire to maintain higher standards for the evaluation of evidence. Radical pluralism and scientific possibilism do not imply scientific or ethical relativism.

There are at least four other key implications of Naess's gestalt ontology. First, the existence of one, interdependent reality tends to curb solipsism. Second, the world we live in spontaneously can no longer be characterized as merely subjective. Expressions such as "the social construction of nature" become oxymoronic. Third, individual organisms exist as knots in a biospherical web or net. Reality is not anthropocentric; it is not particular

to humans. Fourth, humanity can no longer justifiably be seen in opposition to a separate object—nature. This insight tends to temper any “natural” tendencies toward anthropocentrism. As with Leopold’s Land Ethic, people become plain members and citizens of the biotic community, albeit ones with unique powers and proclivities and thus special responsibilities. We are all individual beings, yet we vary in the extent to which we are integrated into the whole.

Humans are massively altering the gestalt character of reality, diminishing it, making it less complex. We do this, Naess argues, without necessarily recognizing we are doing it or the extent to which we are doing it. Thus, we are unable to evaluate the tradeoffs of making such decisions. Naess argues that we generally act simply according to how we “see” reality, but there are aspects of reality that may not be available to us. These aspects are no less there because they are currently unavailable to us, yet they can be destroyed very easily. Sometimes we also confuse our abstract structures of reality (models, data, concepts, etc.) with the contents of reality and vastly underestimate the complexity of internal relations between gestalts, leading ourselves to believe, incorrectly, that higher-order wholes can be reduced to lower-order wholes. It is Naess’s hope that by embracing gestalt ontology, we are encouraged to cultivate our opportunities and faculties for experiencing reality more fully—for experiencing more complex, higher-order gestalts. It is also his hope that we will openly and more carefully consider, in advance, how a proposed research program, action, or decision might affect other peoples’ (or other life-forms’) opportunities for rich spontaneous experiences (consider, for example, the possible impacts of ostensibly beneficial research on nuclear fission or molecular biology). In the end, however, we should remember Naess’s own caution—his description of gestalt ontology is itself an abstract structure. As Naess says, “For me reality has always been something slippery to handle. I seem to grasp it firmly, but like an eel, or even a small lively trout in shallow water, firmness of grasp does not guarantee against escape.”⁶ But does reality really have gestalt character?

Truth—as in *the* truth—is not a defensible notion for Naess. For too many academic philosophers, wonder has been extinguished and replaced by a belief that definitive answers have been found, that the original, initially vexing questions can be laid to rest. Naess is under no such illusion. He views humans as essentially fallible and he sees this domain of fallibility

SERIES EDITOR'S INTRODUCTION

as extending to mathematics and formal logic. This may be why he so freely returns to previously explored material (sometimes just after writing it) and looks at it afresh, with new and frequently competing and even conflicting insights. For Naess, truth is something we seek continually without expecting or believing that it can be found. He seeks peace of mind (*ataraxia*) by suspending judgment (*epoché*). While necessity requires him to take firm positions in life, he often resists taking such positions in his written philosophy. Having reached a general state of mental suspense (*isothenia*), he prefers, as a mature sceptic, anticipating his own tendency to come up with counterarguments and counter-counterarguments, to suggest alternative paths, inspire new ways of looking at things, and foster informed, open-minded debate. This *zetetic* inclination, although nascent in many of his earlier works, was made explicit and became a central theme in his philosophical writings in the 1960s.

For Naess, passivity has no place in philosophy or life. In his famous debate with Sir Alfred Ayer, Naess defines Spinoza's *amor intellectualis* as a "kind of loving attitude towards what you have insight into, while considering it in an extremely wide perspective."⁷ For the mature Naess, *amor intellectualis* involves using his technical and intellectual training to articulate, in direct and forceful ways, his attitudes and evaluations on matters of practical consequence. Like Spinoza and Gandhi, Naess is concerned with human salvation in this world, but Naess, with his concept of "wide-identification," expands this concern to both humankind's relationship to life in general and the self-realization of all life-forms for their own sake. Whether it be understanding how lay people conceptualize truth or experts characterize democracy; considering how our approach to science not only shapes how we do science, but the nature of scientific outcomes too; using philosophy to improve practical communication; facilitating thoughtful debate on the potential dangers of Norway joining the European Union; or discussing the ethics of climbing, the meanings of sustainable development, or distinctions between different approaches for addressing the ecological crisis, Naess seamlessly connects philosophical questioning to activeness in relation to the questions.

Naess's philosophical career can be seen, in one sense, as an attempt to bridge C. P. Snow's two cultures. Believing that the central questions of philosophy are here to stay, he has developed his philosophy over seventy years in part through his effort to relate these questions to the issues of his

rapidly changing, trying, and tumultuous era. Naess's lifelong commitment to integrate interests in nature, science, and logic is evidenced by the mature Naess's championing of philosophical approaches in which both metaphysics and science contribute to all-embracing systems of thought. This approach is particularly prominent in Naess's development of normative systems theory, a strategy for promoting systematic reflection on premises and conclusions. Recognizing that all philosophical questioning must stop somewhere, Naess calls the essential intuitions that serve as bedrock assumptions for our total views, ultimate norms or ultimate premises. Further, recognizing that our philosophical conclusions as well as our lifestyles and everyday actions often appear inconsistent with these ultimate premises, Naess has developed a strategy for using premise-conclusion strings to help identify potential norm conflicts as well as to help assess whether potential agreements and disagreements are real or pseudo. Use of this technique figures prominently in Naess's approach for improving communication, in his approach for exploring both the philosophical basis for Gandhi's *satyāgraha* (active nonviolent resistance) and the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," as well as in his own Ecosophy T.⁸

With regard to total views—broad philosophical systems like Spinoza's, which attempt to communicate our deepest insights and communicate views of life—Naess argues that although the existence of complete, explicit total views is absurd, it is equally absurd to presume to criticize a total view without adopting one (at least implicitly). After relinquishing the possibility of creating a consistent empirical theory of knowledge, Naess came to believe that any theory of knowledge presupposes all major philosophical disciplines, at least on the metalevel. One cannot have a theory of knowledge without presuming a particular reality, at least implicitly, and this necessitates having an ontology, metaphysics, ethics, and so on. This has practical consequences too. We never simply act solely as a philosophy professor who specializes in logic or ethics; we are always, at least partly, mother, daughter, lover, scientist, . . . , and philosopher. If we accept the premise "For every decision we, explicitly or implicitly, take all things into consideration," then the notion of total views or total normative systems can be seen as very "useful fictions," which, if articulated, might help us to improve decision making.

Naess is careful to point out that he sees his own total view and others

SERIES EDITOR'S INTRODUCTION

as fragmentary and constantly evolving—ever “on the way.” Moreover, even if we could have a completely formed and integrated total view, we could not count on being able to articulate it. There will always be a tension between the Spinozistic goal of clarity and the pragmatic reality that in this world we can never wait until all the facts are in. None of these issues, however, justifies abdicating our responsibility to try to articulate our own total views. The mature Naess is a radical pluralist. He believes in defending coherent systems, without claiming that their relation to reality is definitive. While he is committed to the importance of models and systems, he is opposed to the idea that there could or should be a definite worldview. Naess’s hope is that there will be no definite scientific worldview in the future.

No Western philosopher since Descartes—except perhaps Spinoza, who has also been a primary inspiration for Naess—has had the potential to help us drastically reshape our relationship to each other and life in general: not by spelling out *a* clear and coherent total system—to be taken as *the* truth—but by challenging us to articulate our fragmentary total views and connect the abstract problems of philosophy to issues of contemporary social and political conflict. In Naess’s view, “[t]he full meaning of a theory can only reveal itself in practice, and practice is blind without theory.”⁹ To be a philosopher of life, one must embrace both theory and practice and engage them in dance.

In Norway, Arne Naess is regarded as a national treasure, a seeker and a seer, a “minor prophet,” in his own words. His radical pluralism and endorsement of diversity are demonstrated by his complex character. He has a proclivity for being aloof and charming, somber and joyful, accountable and carefree, arrogant and modest, slippery and precise. In a world of contradictions—breathtaking beauty *and* ineffable squalor and suffering—Naess is no exception. He is an antiguru guru. He strives for high levels of consistency and integration in his philosophy but accepts that in his personal life he cannot live up to his philosophical systems’ requirements. He strives for definiteness of intention, yet he appreciates vagueness and eschews dogma, refusing to be pinned down to a particular viewpoint or placed in a particular philosophical camp. This stance is further supported by his sometimes maddening tendency to revise, revise, and re-revise. As a consequence, one cannot go to any of his books or articles and find the “definitive” Arne Naess. He is a

troublemaker too, but the kind of troublemaker people want to have around because he challenges orthodoxies with an elfin irreverence. Naess stands out because his frequently outlandish and controversial views are felt deeply, reasoned carefully, and conveyed playfully.

Naess has had a profound influence on Norwegian academic life and the society as a whole. From 1939 to 1954 he was Norway's only professor of philosophy. He was chiefly responsible for organizing courses for the *examen philosophicum*, introductory examinations in logic, methodology, and history of philosophy that an entire generation of undergraduates (roughly 100,000 people) were required to take, regardless of their disciplinary focus. His unique paradigm of inquiry—emphasizing open-mindedness, empirical analysis, pluralism, a thorough grounding in philosophy and the history of ideas, and a vital concern for contemporary problems—is credited with shaping the intellectual fabric of postwar Norway. At a press conference for Naess's eightieth birthday, the Norwegian Minister of Education testified to the significance of the Norwegian version of Naess's *Communication and Argument*, one of the primary texts for the *examen philosophicum*. "We have all read it. We *still* cheat in argumentation, but now with feelings of guilt."¹⁰

Naess is also credited with rekindling the study of philosophy in Norway and with forming the Oslo school of philosophy. The section on Scandinavian philosophy in *The Encyclopedia of Philosophy* elaborates:¹¹

The philosophical milieu in Norway today [circa 1967] is determined by an internationally known and original philosopher. . . . Arne Naess . . . is the originator of a radical type of empirical semantics and the leader of the so-called Oslo group. . . . The empirical methods applied by the Oslo group employ carefully worked-out questionnaires. By the help of such questionnaires and by teamwork, philosophers of the Oslo group have carried out investigations of such expressions as "truth," "democracy," and "private enterprise." . . . If it is correct that Norwegian philosophy has had a dead period,¹² it is equally correct to assert that, primarily because of Arne Naess, Norwegian philosophy is now in the middle of a period of life and growth.

When asked to comment on this passage, Naess was emphatic about inserting an addendum to the last sentence.¹³ He was proud to convey that contemporary Norwegian philosophers pursue a wide variety of directions and employ a diversity of approaches, many independent of Naess's own line. This point is borne out by the more than forty-four permanent teaching positions currently at the University of Oslo's Institute of Philosophy

SERIES EDITOR'S INTRODUCTION

and the broad spectrum of approaches these philosophers pursue, from the analytic tradition to phenomenology and from existentialism to hermeneutics. As one of Naess's successors, Alastair Hannay, in his section on Norwegian philosophy in the *Oxford Companion to Philosophy*, has commented, "Norway enjoys a varied and vigorous philosophical life. . . . Philosophy's place in Norwegian academic life, as in the society at large, is due in large measure to Naess."¹⁴

The reach of Naess's contributions to philosophy and social research extends well beyond Norway. Significant international recognition has also come his way for these contributions. He has received the Peer Gynt Prize awarded by the Norwegian Parliament (2004), the Nature and Environment Prize from the Nordic Council (2002), the Nordic Prize from the Swedish Academy (1996), the Mahatma Gandhi Prize for Non-violent Peace (1994), and the Sonning Prize for contributions to European culture—Denmark's version of the Nobel Prize (1977). He has even been honored by five festschrifts, one each for the occasions of his seventieth, eightieth, and eighty-second birthdays and two for his eighty-fifth birthday.¹⁵ He is the founding editor of the influential journal, *Inquiry*, created to promote collaboration between philosophers and social scientists. He is also a renowned mountaineer and climber, an occasional nonviolent political activist, and father of the deep ecology movement. His social concern, sense of wonder, and trickster nature have all contributed to his success at numerous academic posts around the world—preferably near mountains or deserts—from Berkeley to Jerusalem and Helsinki to Hangzhou. He is, to this day, still a frequent international speaker.

Even with this high level of accomplishment, the significance of his work as a whole—as a gestalt—has yet to receive broad-scale appreciation outside of Scandinavia. There are many explanations for this situation.

The overarching reason has likely been the general inaccessibility of his oeuvre. This inaccessibility has many facets. Naess has been incredibly prolific, producing over four hundred publications, more than thirty of which are books. These publications span topics from argumentation theory to zeteticism, with adventures along the way at such seemingly incongruous destinations as climbing ethics, cultural anthropology, and deep ecology. His range of topics—in abundance, breadth, and depth—is trying, at best, for our increasingly compartmentalized and specialized academic communities.

In addition, the bulk of his most significant works have been out of

print for quite some time. Many of the earlier editions of the books were edited poorly and documented sparsely. A significant portion of his important articles and book chapters appears in obscure or difficult-to-find books and journals, and much of his work has remained unpublished (at least two hundred papers and several book-length manuscripts). Naess's main works appear in three primary languages, German, Norwegian, and English, although he has also written in Danish, Swedish, and French. Finally, Naess's prose can be dense and opaque, if not downright confusing. Although this trait is by no means unusual for a philosopher, when blended with Naess's appreciation for vagueness and ambiguity, his aversion to authoritative stances, and his tendency to revisit topics by reconsidering earlier viewpoints, the already high entrance fee can become prohibitive.

The boundless range of Naess's interests and the general inaccessibility of his entire oeuvre have led some scholars to view him rather pejoratively as a dilettante. Some of these critics view him as flitting from one area of interest to another, not mining any to its logical conclusion; some see him as throwing away a great talent in logic; some view his social research, especially his work with questionnaires on lay people's and experts' perceptions of philosophical concepts and his use of statistics, as outside the realm of serious, professional philosophy; and still others see him as inappropriately conjoining his philosophy with activism. His breadth has even led a few of the more extreme critics to dismiss his work out of hand. Although some of the criticisms detailed above do have merit, in my view Naess gives the dilettante a good name.

To address this range of concerns, the *Selected Works* project was conceived. The project was the brainchild of Douglas Tompkins. "Miracle Doug," as Arne refers to him, is the founder of the Foundation for Deep Ecology and is himself a renowned climber and kayaker in addition to being a wildlands philanthropist who has helped protect immense tracts of land in Chile and Argentina, some as large as Yosemite. The *Selected Works* would have simply remained a "great idea" without Doug's generosity and support. The project was initiated in 1994 and commenced editorial work in 1996 under my direction.

In the introduction to his *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, and Sartre* (1968), Naess decries the condition whereby the philosophical life of an individual is set by the local philosophical scene, by provincial biases, or by what is easily accessible.¹⁶ Such accidents of envi-

SERIES EDITOR'S INTRODUCTION

ronment should not, in Naess's view, play a pivotal role in shaping a budding philosopher's development. I see the *Selected Works*, at least in part, as a response to this predicament.

The purpose of the *Selected Works* is to bring—for the first time—the full scope of Naess's philosophical contributions to the English-language audience in one collection of highly readable and meticulously edited volumes that adhere to the highest standards of contemporary academic philosophical publishing. The *Selected Works* is, however, by no means exhaustive; it is not a collected works.¹⁷ We have simply aspired through careful selection to offer a representative and relatively expansive collection of Naess's principal writings. As such, the *Selected Works* is the definitive repository of Naess's oeuvre, chronicling the development and progression of his thinking for scholars, students, and critics alike.

In the remainder of this essay, I attempt to sketch briefly one possible version of an intellectual biography for Arne Naess. I endeavor to trace some key influences on Naess's philosophical development, discuss the evolution of his philosophical outlook, and touch on the relevance and significance of each volume in the *Selected Works*. I close with a short note on our editorial approach.

From Scientism to Wisdom: Toward a Philosophy of Life

The philosophic researcher should be task-minded, not discipline-minded, and should follow his questions wherever they lead.

Arne Naess, "Norway"

Arne Dekke Eide Naess was born in 1912 in the dining room of a large house with a wild, expansive garden. The house was on the outskirts of Oslo in Slemdal, a short walk from where Naess lives today. Arne was the unplanned fourth child of a wealthy family from Bergen. Before he was a year old, his father, who was ill with cancer, had died. Overwhelmed, his mother, Christine, entrusted little Arne to the family's governess. This is where his first memories begin.

Arne speaks of Mina, his governess, endearingly. She is described as satisfying little Arne's every wish, be it procuring live flies for his bath or bringing a trunk filled with bottles on a family trip so that he could continue his water-play experiments. Sometime before Arne was four, Christine dismissed Mina, ostensibly for spoiling Arne too much. This initiated a deep

rift between Arne and his mother, which was never to be mended. It also set in place a sense of loss, alienation, and resistance to emotion that profoundly influenced Naess's early personal and philosophical development.

Significantly later, after an intensive six-day-a-week, fourteen-month psychoanalysis with Freud's noted collaborator Dr. Edvard Hitschmann, Naess came to understand his impenetrable shell that keeps others at arm's length (*Panzercharakter*, in Freudian terms) as resulting from a reaction to his mother's unreliability and emotional hysteria. His effort to keep his mother at a distance morphed into a general aloofness and distancing. The adolescent Arne began to favor an "objective," bureaucratic approach to language. He saw art, music, and poetry as being seduced by emotion, by beauty and form, but viewed science and philosophy as realms from which such emotions should be banished. This prejudice would take decades to overthrow. At this time he also developed a single-mindedness and resistance to inconvenience and pain that to this day make it easier for him to concentrate and focus. As Hitschmann pointed out, however, this inward turn has a flip side, a certain self-destructive or masochistic bent that was later to plague him, particularly in his relationships with women and his children.

Much of Arne's early childhood was spent at the seashore, and this is the period in which his interest in nature and experimentation began to flourish. Feeling somewhat distanced in his relations with people, he identified with nature, especially little sea creatures. He waded in shallow water for hours, inventing experiments to test nascent hypotheses about the behavior of small sole, tiny translucent shrimp, and crabs. He describes these experiments as engendering an early enthusiasm for diversity and a tendency to suspend judgment on the nobility or status of different beings. He loved these creatures for their unique qualities and their amusing adaptations and limitations. They inspired a certain egalitarianism, which took hold and later influenced his philosophical approach in profound ways.

Young Arne was restless. He had an early penchant for "collecting" and organizing large groups of numbers, stones, and stamps. He started climbing trees in the family's little "wilderness" before he was five and soon progressed to big firs and spruces. He found that he enjoyed being able to watch people from above. Arne outgrew trees fast. His desire for perspective and the opportunity to survey broad areas was rapidly transferred to mountains. At the age of five, he began going to his mother's small moun-

SERIES EDITOR'S INTRODUCTION

tain cottage in the town of Ustaoset, high in the Hardangervidda between Oslo and Bergen. By the age of eight, he had adopted Hallingskarvet, a bread-loaf-shaped mountain about three and a half hours' walk from Ustaoset, as his surrogate father. In his teenage years, this obsession for expansive perspectives translated into a lifelong passion for mountaineering. When Naess was sixteen or seventeen he climbed the 106 tallest mountains in Norway. It was around this time that he was first introduced to Spinoza's *Ethics* by a Norwegian Supreme Court justice that he met in the mountains. Naess's desire for a broad and open perspective, for seeing things in totalities (god's-eye view), translated to his studies. Young Naess read widely in economics (especially value theory), science, philosophy, history of philosophy, and the Earth's biological history.¹⁸ This commitment to cultivate an ever-expanding perspective would later potently influence his approach to philosophy.

Arne's youth was spent captivated by piano, study, and mountains. His decade-older brothers took it upon themselves to toughen up their timid younger brother, as well as introduce him to the ways of the world and scholarship. When Arne was only eight, his eldest brother, Ragnar, left for America to study for a Ph.D. in chemistry at MIT. Ragnar later went on to receive one of the Harvard Business School's first degrees and became a successful stockbroker in the United States. Erling studied economics and went on to create an international shipping empire; he became famous for his assistance to the Norwegian government-in-exile during the Nazi occupation. His sister, Kiki, married a German doctor and after the Second World War returned to Norway to become a physical therapist. From Kiki he learned the power and significance of offering encouragement to others. During his early years and well into adulthood, Arne's tight-knit relationship with his siblings provided security and support for him to "find his own way"—*sva mārga*, to use one of his favorite Sanskrit terms. Although he tended not to seek their financial assistance, his wealthy and generous brothers offered a sense of comfort, safety, and the occasional extravagance, which in later life made it easier for him to live his bon mot, "simple means, rich ends."

Naess studied philosophy, mathematics, and astronomy at the University of Oslo. At nineteen, after completing the equivalent of an undergraduate degree, he left Oslo to continue his studies in Paris. Naess was put off by the adoration Bergson received in Paris, but ultimately left to seek

broader vantage points, cheaper living, and better climbing opportunities. After completing two master's theses at twenty-one, one exploring discussion about the concept of truth and the other exploring the use of behavioral psychological principles to judge truth validity, Naess left Oslo again, this time for Vienna. In Vienna he took master classes in piano, where, following his trickster nature and as a response to the strict taskmaster Fuchs, he "learned" new material. When he ran out of pieces he had long since mastered, he quit. Thinking that it was necessary for philosophers to have high levels of self-knowledge, he underwent intensive psychoanalysis with Dr. Edvard Hitschmann. As a part of that process he assisted with the treatment of patients in a psychiatric hospital and developed tremendous empathy for the suffering of humankind. While in Vienna, he was also warmly welcomed at the famous Schlick seminar.

The logical empiricists' friendly, equiminded approach to discussion made a great impression on Naess, but he was not equally affected by their ideas.¹⁹ The young Arne was impressed by the preciseness, empirical nature, and lack of emotion in science—he wanted to practice philosophy with a scientific bent and he wanted to test philosophical hypotheses with experiments. He was already interested in perennial philosophical problems and did not believe that most of them were ultimately pseudoproblems that could be solved by investigating inconsistencies in language. His most significant philosophical issue with the logical empiricists was not that they were empirical, although he believed they were misguided in thinking that any philosophical problem could be wholly empirical, but that they were ultimately antiempirical in their belief that a logical grammar of language was more suitable for investigating the use of terms than statistical analysis of their actual use. Naess's detailed critique of the logical empiricists' position and reflections on his personal experiences attending the Schlick seminar appear in volume VIII. In this critique, Naess expresses a concern that in their interpretation of terms, many philosophers (not just the logical empiricists) were artificially constricting the range of possible interpretations and thus unintentionally reducing potential insights regarding the diversity of tenable positions on problems of vital concern. This perspective presaged his later views, particularly those expressed in *Interpretation and Preciseness* (SWAN I), and his later approach to cultural anthropology and philosophy of science. Naess sums up his general perspective on the state of philosophy at the time with the following remark: "The

turn of (Western) philosophy in [the twentieth century] towards language rather than cosmos, towards logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind-alley."²⁰

While in Vienna for fourteen months in 1934 and 1935, Naess made final revisions to his doctoral thesis, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior).²¹ Although Naess drew inspiration early on from Russell and Whitehead, his doctoral thesis can be seen, in part, as support of the American Pragmatists (James and Dewey) in opposition to Russell and early Wittgenstein. According to Dewey, the main purpose of his philosophical writings was "to reintegrate human knowledge and activity in the general framework of reality and natural processes."²² Naess did just this by creating a radical and unique approach for exploring how high science is performed, a sort of science of science. At this point, Naess believed it was possible to use such an approach to obtain a complete account of all science within one system. Inspired by the ethologist Uexküll's "special biology" (*Umweltforschung*), Tolman's "objective" behavioral psychology ("molar" behaviorism), and the cultural anthropologist Malinowski's work on speech and nonverbal behavior, Naess took on the standpoint of a neutral, nonparticipant spectator and outlined a program for an empirical metascience of science, an ethological approach to epistemology of science.

Naess used the idea of a dispassionate visitor from another solar system coming to study Earth-based scientists to demonstrate the possibility of completely describing both the activity of researchers and the contents of knowledge without drawing on the subjective models that governed traditional epistemology and presupposed knowing subjects or minds. The idea was to study or rather "witness" science similar to the way experimental psychologists study rats, but without falling into the trap of imposing their own experience of reality and their preexisting conceptual models of reality ("maze epistemology"), or their scientific pretensions. In the view described in *Erkenntnis*, knowledge is cognition—it is an activity with intention—and this helps to dismantle the subjectivist dualism between the content of knowledge and the activity of research. Naess's interest was in describing these patterns of research activity. He argued that the *terminology* associated with scientific activity—which is bound to the subjective-reality model—changes in leaps and bounds, not the *patterns of research activity*, which are in constant, but gradual, flux. With this argument that

change in science happens gradually, by generalization and differentiation, Naess foreshadowed his response to Kuhn well before *The Structure of Scientific Revolutions* was published in 1962.

With *Erkenntnis*, Naess also anticipated ideas that later became prominent in linguistic philosophy, such as the importance of ordinary language over formal systems and the importance of using observation of contrasts and discriminations to build up understanding of systems. In the end, presaging his own radical pluralism to come, Naess seems to relax his early position on the importance and possibility of creating a metascience of science from the “far outside” and ultimately comes to view subjective and behavioral models as two different point-of-departure formulations in an indefinite plurality of equally valid approaches for a metascience of science. This refined perspective is taken up in Naess's 1965 article “Science as behavior” (in SWAN IX), which returns to the prospects and limitations of creating a behavioral metascience to study the scientific enterprise, but this time from the “near outside.”

At age twenty-four, after receiving his Ph.D. from the University of Oslo for his work on science as behavior, Naess returned to his interest in the problem of truth. A particular concern was the inadequacy of philosophers' intuitive methods for capturing how lay people conceived and used the term *true*. In 1937 and 1938 he developed and tested an empirical approach for using questionnaires and statistical analysis to investigate non-philosophers “commonsense” views on the notion of truth. He then related these notions to philosophers' theories of truth. Naess found an amazing diversity of views among the amateurs. He also found that their views, although typically devoid of philosophical pretensions, generally covered the views represented by professional philosophers. This work elicited substantial controversy, most of which came from philosophers who viewed it as undignified to use questionnaires and statistics to investigate one of the great problems of humanity. Naess's results were published as “*Truth as Conceived by Those Who Are Not Professional Philosophers* (1938). A summary of this work is presented in Naess's “Common Sense and Truth” (in SWAN VIII). Naess's continued application and refinement of these techniques would evolve into empirical semantics.

In 1937 Naess fortified his lifelong fascination with the arctic climate Hallingskarvet by building Tvergastein, his now-famous rustic and remote hut, at its base, a three-and-a-half-hour trek from the train station at Us-

SERIES EDITOR'S INTRODUCTION

taoaset. He outfitted the hut with Rube Goldberg oil lamps that also served as stoves for warming tea and with an eclectic library of teach-yourself language manuals, Sanskrit-English dictionaries, astronomical and wildlife field guides, novels by Dostoyevsky and Ibsen, letters of Spinoza, and a complete philosophy library. Following his passion for amateur science he also created “institutes” of petrology, chemistry, zoology, hydrology, and botany at Tvergastein. Naess has written the bulk of his work at Tvergastein and spent the equivalent of about twelve of his ninety-two years living there. The enormous open views at Tvergastein afforded Naess the distance and perspective he so craved while insulating him from philosophic fashion and dogma. Here he had the luxury, freedom, and good fortune to pursue his own interests free from the banalities and distractions of academic life. After completing what is now Tvergastein's main room, Naess went on to perform postdoctoral research at Berkeley (1938–39) with the pioneer of empirical psychology, E. C. Tolman. At Berkeley, he went from studying the behavior of rats faced with many possible alternatives to studying the behavior of the scientists studying the rats.

Naess returned to Oslo in 1939 to be appointed to the University of Oslo's Chair of Philosophy at the age of twenty-seven. On April 9, 1940, German forces invaded Norway; it would remain under Nazi rule for the next five years. This was a harrowing time for academics throughout Europe. Arne tried to maintain his unruffledness, pouring himself into research and curricular reform initiatives intended to widen and expand the perspective of university undergraduates. He tried to stay at Tvergastein often, and this afforded him some peace and solace in a world of great tension. Before long, however, even he was drawn into the resistance movement. In the fall of 1943 he played a central role in foiling a Nazi attempt to deport University of Oslo students to concentration camps for “reeducation.” The University was subsequently closed and Naess became even more committed to the resistance movement and his research. By this time he had developed great admiration for Gandhi's catalytic 1930 *satyāgraha* campaign, the march to Dandi in protest of the British salt tax. Naess was greatly impressed with Gandhi's idea of trying to meet one's opponent in a manner that would calm passions and facilitate truthful communication. He thought such an approach could have had a significant effect on quenching the Nazi expansion, *if* the necessary infrastructure to support *satyāgraha* had been created in European countries. After the war,

Naess used these insights in his efforts to bring together suspected torturers and the families of torture victims to gain a sense of closure on the fate of their loved ones—and to avoid having the “traitors” subjected to equally horrid persecution. In 1948 Naess was invited to be the scientific leader of a new UNESCO project created to explore ideological controversies between the East and the West. He was soon off to Paris again, this time to pursue his interest in using philosophy to address questions of social and political importance.

The Cold War was a tinderbox and two core ideological conflicts revolved around use of the terms *democracy* and *freedom*. Naess was asked to address both but countered that UNESCO's requirement that he deliver a report within one year made it essential for him to consider *democracy* first. His goals were to clarify what people mean when they use the term *democracy* and to understand the causes of ambiguity and confusion that result from its use. After an extensive literature review, which chronicled historical usage of the term, Naess and his assistant, Stein Rokkan, prepared a thirty-question survey that was distributed to almost 600 international experts in the fields of philosophy, law, history, political science, sociology, economics, communications, and logic. Naess used the roughly 100 replies to create an empirical study of “agreements” and “disagreements.” The study demonstrated *democracy's* richness, diversity, and multiplicity of meanings and thus undermined its misuse in both the East and the West. This incited detractors from every ideology, who roundly criticized the resulting report, *Democracy in a World of Tensions*, which according to Naess “was promptly sold out and never reprinted by UNESCO due to the politically dangerous character of its items.”²³ Naess's “Analytical Survey of Agreements and Disagreements,” along with two other pieces on ideological convictions and rationality, appears in SWAN IX.

The UNESCO democracy study was the first and last international, large-scale application of Naess's empirical semantics approach. He was originally interested in doing another study on “cultural diversity,” but neither this nor the “freedom” study came to fruition. Naess learned—much to his chagrin, and as his superiors had warned—that UNESCO was a place for writing reports; it was no place for conducting research. Naess's frustration with the UNESCO experience and his wanderlust for the perspective of mountains led him to daydream first, and then to “pursue non-essentials”:²⁴

SERIES EDITOR'S INTRODUCTION

The arguments against abandoning the imaginary joys of the Himalayas for an actual expedition seemed strong to me, and so they still do. But in the autumn of 1948 the longing for the mountains pushed aside all sensible considerations. For the first time since I was twelve years old, I had to do without a summer holiday in the mountains. The safety valve guarding one against exaggerated climbing expeditions was thus removed. Added to this came the great disappointment in my own work. Lured by UNESCO's plans of philosophical research into international ideological conflicts, I had been tied up in Paris for nine months. Such large-scale extravagant schemes prove, however, impracticable. Too much nationalism and too little belief in research prevented UNESCO from getting the number of nations to subscribe to such long term schemes. By the way of compensation, I indulged at night in delightful trips to the Alps. As the situation got worse, this was, however, not sufficient compensation; the material was exhausted. Then my fantasies took me to the Caucasus. Later I had to go all the way to Persia, Afghanistan, Hindu Kush and India, and so I was committed.²⁵

Although Naess's research interests and total view continued to evolve after 1953, the general philosophical approach of the mature Naess, outlined at the beginning of this essay, was basically in place. Naess has described his philosophical work as falling into four periods or phases. From the mid-1930s until about 1940, he focused on philosophy of science. Then until about 1953, he concentrated on empirical semantics. A short period, surrounding the publication in 1968 of his major work on the zetetic scepticism of Pyrrho, ends when, at the pinnacle of his philosophical career, he sought early retirement in 1969 to devote himself more fully to ecological issues and activism. Naess has commented that this effort to be more actively engaged in social and political conflicts reflects his desire "to live rather than function." This view adequately reflects coarse, general trends, but it fails to do justice to Naess's philosophical approach, which has him mine a larger range of topics and return to them in a helical fashion throughout his life. I would rather describe his work as falling into thematic areas that were picked up, sometimes put on ice, but returned to periodically throughout his life. Although I concur that the period after his formal retirement can be seen as emphasizing ecological philosophy and activism, the two decades between 1960 and 1980 also represent a period of considerable productivity on conventional academic philosophical topics. It was in those decades that Naess produced important work, especially, on

scientific and cultural pluralism, Gandhi and Spinoza scholarship, history of philosophy and philosophy education, and normative systems theory. He has written on a wide range of important philosophical topics even into the 1990s and beyond, during which time he produced, among other works, his *Life's Philosophy* (2002; coauthored with Per Ingvar Haukeland), introductions to the philosophy of Gandhi (2000) and Spinoza (1999), and *Introduction to General Relativity and Its Mathematics* (1998; coauthored with Øyvind Grøn).²⁶ An adequate sketch of Naess's subsequent research interests and philosophical development can be gleaned from the following brief discussion of the volumes in the *Selected Works* and the discussion, at the end, of how his earlier work figures into the evolution and exegesis of deep ecology.

Naess's best-known philosophical work is likely *Interpretation and Preciseness*, published in 1953 (SWAN I). It is an attempt to convince the world of analytical philosophy about the types of approaches that are necessary, from the standpoint of a radical empiricist, to adequately interpret terms and point-of-departure statements (T_0 statements), given the manifold of plausible interpretations. It highlights the role and potential of experience in relation to intuition and reflection by requiring that every direct or implied hypothesis regarding the actual use of terms, phrases, or sentences be testable. In addition, it responds to the ostensibly antiphilosophical sentiment in *Erkenntnis* by clarifying the function of and relationship between point-of-departure statements and precizations. In Naess's semantics, the most general statements, T_0 statements (words or sentences), are phrased in ordinary language and are intended to be philosophically neutral. T_0 statements serve as points of departure for investigations of possible interpretations. When a new interpretation of an expression eliminates some of the ambiguity of a preceding interpretation, without adding any new ambiguity, it is said to be a "precization." Thus, a sentence T_1 is more precise than a sentence T_0 when every plausible interpretation of T_1 is also a plausible interpretation of T_0 but at least one plausible interpretation of T_0 is not a plausible interpretation of T_1 . This process of using successive differentiation to better understand people's interpretations of terms, phrases, or sentences can go on almost ad infinitum; it is limited only by time, resources, imagination, and willing test subjects. With this process, however, Naess has created a formal approach for classifying different statements (interpretations) based on users' "depth of intention," the point at which they no longer, explicitly or implicitly, accept or embrace higher levels of precization. A focal point is

SERIES EDITOR'S INTRODUCTION

Naess's approach of directly employing surveys to explore systematically and empirically the meanings of terms, phrases, or sentences based on their occurrences. Naess also created a formal procedure for comparing occurrences, both interpersonal and intrapersonal, that involves performing tests for different forms of synonymy. Naess has applied his empirical semantics approach to explore the meanings of "truth," "democracy," "it is the case," "certain," "perfectly certain," and "extremely probable" (see SWAN VIII for additional details on and applications of empirical semantics).

In *Scepticism* (SWAN II), published in 1968, Naess takes on the generally accepted position that scepticism, if widely embraced, leads to the intuitively false conclusion that we cannot know anything. Naess explores the variety of historical interpretations of scepticism in light of Sextus Empiricus's outline of Pyrrhonian scepticism. Three categories of philosophical positions on the question of truth are considered: Dogmatists claim at least one truth, Academicians negate the possibility of finding any truths, and Pyrrhonists neither assert that they have found any truths nor assert the impossibility of finding one. Naess takes a sympathetic view of this last group, arguing that this form of zeteticism can represent both a viable philosophical position and a way of life that supports positive mental health. What ultimately sets this position apart is not that supporters are fundamentally opposed to making acts of assertion, to stating that "something is the case," but that they do not make such assertions with the conviction of truth. Naess also uses empirical semantics to demonstrate support for this position on rational and epistemological grounds. Distinguishing between one's philosophical view and the necessity of firm, socially responsible action in everyday life, he also responds to the common notion that this radical nondogmatism generally leads to paralysis of action. In the end, Naess argues that adopting this updated view of Pyrrhonic scepticism could lead to quite the opposite, a more open-minded approach to philosophy and life. Further elaborations on particular aspects of Naess's Pyrrhonism along with a response to Rescher's reappraisal of scepticism appear in SWAN VIII.

Which World Is the Real One? (SWAN III), which was first published in 1969 and revised in 1982, is, in part, an attempt to reinvigorate appreciation and study of the broad variety of philosophical outlooks and total views that exist in Chinese, Indian, Greek, Western, comparative, and recent philosophy. It makes use of Naess's empirical semantics, developed in *Interpretation*

and Preciseness, to argue that it is an illusion to assert that combined scientific and philosophical or “purely” philosophical syntheses of such total views can exist. Naess argues that the results of science cannot be integrated into any single world picture, in part because such attempts at synthesis are necessarily fragmentary and because valid multiplicities of syntheses exist. He also takes up the question of the comparability of total views. Such comparisons, although important, are inevitably shaky because, despite admirable aspirations for standing back to obtain a meta-perspective, real people can never totally throw off their own total views; regardless of how explicit those views may be or of how conscious of them their holders are, biases are unavoidable. We always have our own perspective to contend with. For Naess the inevitable conclusion is that pluralism is inescapable and nothing to lament. He combines these points of view with a discussion of cultural anthropology to argue for the critical importance of supporting the flourishing of rich cultural diversity. Additional articles elaborating themes related to the significance of maintaining cultural diversity and its relationship to ecological sustainability appear in SWAN X.

In *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), published in 1972, Naess suggests that scientific theories must be understood in the wider context of the plural rationalities from which they spring. Science is not autonomous. Nor can it be seen justifiably as arising independently from the general enterprise of building philosophical systems. Furthermore, the relationship of models to reality is always indirect. This volume should be seen as an effort to erode the popular misconception of science as infallible and a viable surrogate for religion, not as an attempt to build a unified theory of science within one system, which Naess had long since rejected. Because no theory can ever be either fully verified or falsified, there exists a significant freedom of choice in both modes of exploration and theories that one can tentatively adopt. The notion of “fundamental theories” is immediately called into question. As the undemonstrated (and often undemonstrable) assumptions upon which theories rest are changed, a huge multiplicity of possibilities for future theory development arises, thus possibly helping to inspire a renewed enthusiasm in science by broadening our concept of rationality and restoring the role of imagination. Articles extending or elaborating on the ideas in *The Pluralist and Possibilist Aspect of the Scientific Enterprise* appear in SWAN IX.

Naess's third book on Gandhi, *Gandhi and Group Conflict* (SWAN V),

SERIES EDITOR'S INTRODUCTION

was published in 1974. This book develops an intellectually rigorous presentation of the theory of *satyāgraha*—the way of militant nonviolent resistance—as a strategy for conflict resolution. This work is a paradigmatic example of Naess's approach to research and writing. As the eminent Norwegian social scientist and peace researcher Johan Galtung has suggested, Naess's 1955 *Gandhis Politiske Etikk* (Gandhi's political ethics)—with Galtung—and his 1965 *Gandhi and the Nuclear Age*, along with his articles that analyze or extend on Gandhi's work (see SWAN IX and X), act as exercises or drafts for this, his major work on Gandhi.²⁷ Using Gandhi's own recorded accounts, Naess explores the norms and hypotheses tacitly employed by Gandhi in his nonviolent campaigns and then uses these to create the first philosophical and logical systematization of Gandhi's approach to militant nonviolence. A careful investigation of Gandhi's two ultimate norms (as interpreted by Naess), "Seek complete self-realization" and "Seek truth," and his belief in *advaita* (nonduality), along with a consideration of their parallels to Spinoza's unity thesis, will reveal interesting insights into Naess own characterization and use of "Self-realization!" as the single ultimate norm of his Ecosophy T. Naess also considers Gandhi's approach to nonviolent conflict resolution in light of contemporary reactions against the use of nonviolence by Frantz Fanon, Malcolm X, Stokely Carmichael, C. V. Hamilton, and Sartre. He then examines Gandhi's ideas and intentions regarding group conflict in light of the ideas and intentions underlying other modern philosophies of conflict, including those of Luther, Nietzsche, Tolstoy, and Jaspers.

In *Freedom, Emotion, and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics* (SWAN VI), Naess uses symbolic logic to present a formalization and partial reconstruction of a small but important part of the *Ethics*. Spinoza's system is embedded in the seventeenth century and expressed in Medieval Latin. Two of Naess's goals are to bring empirical analysis to bear in trying to interpret and update Spinoza's system and to make Spinoza's insights more accessible and relevant to contemporary readers. To perform his reconstruction, Naess draws heavily on a small book he produced in 1962, *Equivalent Terms and Notions in Spinoza's Ethics*, which lists and discusses 243 equivalences that are directly asserted or suggested by Spinoza in the *Ethics*, according to Naess.²⁸ Accepting the transitivity of the equivalence relations as a general rule, Naess argues that a vast array of structural relations can be elucidated (many of these are often only suggested or implicitly asserted by

Spinoza). One of Naess's key conclusions is that every living thing is to some extent "in itself" and to some extent "in something else" due to the presumed gestalt nature of reality. Another is that the terms *substance*, *attribute*, *God*, *mode*, and *Nature* are "expendable"; Spinoza's basic nondualism is made clearer by Naess. A third conclusion is that *to be active* and *to understand* cannot be systematically distinguished in the *Ethics*. This notion, which has important implications for philosophy of science, is also embedded in Naess's conclusion in *Erkenntnis* that knowledge is cognition—the content of knowledge and the activity of research cannot be cleanly separated. Naess uses his analysis to explicate three main themes of Spinoza's system: the importance of a notion of uncoerced freedom (not coerced by externals), the importance of developing and acting on strong emotions to make progress in achieving higher levels of freedom, and the importance of joy that activates the complete person (as opposed to joy that simply activates part of the body or the soul). By clarifying the semantic structure of a central part of the *Ethics* with his own logical structure, Naess explains that there exists a wide variety of possible interpretations of the contents of the *Ethics*. Articles on Spinoza's determinism and its relationship to freedom, Spinoza and Māhāyana Buddhism, "Spinoza's Finite God," and other Spinoza-related topics appear in SWAN IX. Articles that explore Spinoza as an inspiration for deep ecology appear in SWAN X.

The English translation of *Communication and Argument: Elements of Applied Semantics* (SWAN VII), which was first published in 1966, is largely a popularization of the central ideas in *Interpretation and Preciseness*. The English edition is a somewhat watered-down version (no exercises) of the Norwegian edition that from 1941 to 1969 was used by nearly 100,000 university students in the *examen philosophicum*. Its purpose, to quote the *Times Literary Supplement*, is " . . .to teach people in a democratic society to think clearly, coherently, and above all responsibly." Naess's hope is that teachers use controversial examples from current events—the more emotional the better—to confront students with their own confusion and encourage them to strive for higher levels of depth of intention. The final chapter outlines six "Gandhian" rules of effective discussion, which emphasize avoiding six forms of "irrelevance in discussion."

The first two volumes of selected papers (SWAN VIII and IX) contain important material that is not covered by the preceding volumes, material that complements them, or material that builds on or reevaluates positions

SERIES EDITOR'S INTRODUCTION

taken earlier. Volume VIII includes sections on "Empirical Semantics and 'Truth,'" "Zeteticism," "Empiricism, Possibilism, and Pluralism," and "Metaphysics, Morals, and Gestalt Ontology." Volume IX includes sections on "Democracy, Ideology, and Rationality," "Philosophy of Science," "The Philosophy of Peace, Gandhian Ethics, and Communication," "Spinoza," and "Philosophical Development, Environment, and Education" (which includes an autobiographical article describing key influences in Naess's philosophical evolution, "How My Philosophy Seemed to Develop" and an interview, "Deep Ecology and Education"). A number of the especially significant articles have already been referred to, where relevant, in the discussion of Naess's philosophical evolution; other articles are discussed in the notes.

Today, Naess is, perhaps, best known for his "deep ecology" writings, the topic of *Deep Ecology of Wisdom* (SWAN X). This work began with a short unpublished paper written in 1965, "Nature ebbing out" (in SWAN X), and continues to this day. As the primary architect of deep ecology, Naess has more than seventy-five published articles and book chapters and more than sixty unpublished pieces on this topic. His only book-length discussion of deep ecology began with a short mimeograph, *Økologi og Filosofi* (Ecology and philosophy), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi, Samfunn og Livsstil* (Ecology, community, and lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. This book has not been included in the *Selected Works* because it is widely available and currently in print.

Volume X is the first comprehensive collection of Naess's work on deep ecology—it includes a broad array of articles on its history, influences, theory, development, practice, and prospects. This volume shows how deep ecology represents the integration and culmination of Naess's lifelong interests in philosophy, social research, activism, science, and nature. It demonstrates how Naess, in his explication and elaboration of deep ecology, draws extensively from both his life experience and his research on empirical semantics, scientific and cultural pluralism, Pyrrhonic scepticism, Spinozistic nondualism and activeness in relation to problems, gestalt ontology, normative systems theory, total views, and Gandhi's concepts of self-realization and nonviolent communication. Volume X also shows how Naess's approach to deep ecology has unfolded over time, with substantial emendation, in part as a response to the worsening ecological crisis, in part to answer criticisms that deep ecology was turning into a cult or religion,

and in part to address the considerable confusion and controversy that arose from his use of provocative terminology and philosophical vagueness.

Ever since he coined the term *deep ecology* with his now famous paper "The shallow and the deep, long-range ecology movement: A summary," (in SWAN X) given at the 1972 Third World Future Conference in Bucharest, Naess's central concern has been to use philosophy and philosophical thinking to help humans overcome the ecological crisis and, ultimately, to restore the Earth to a state of rich and flourishing biological and cultural diversity (see volume X). A basic premise is that some ethical norms, particularly those grounded in spontaneous experience, can be tentatively accepted as objectively valid. An example for Naess would be the statement that "Every living being has an equal right to live and flourish, *in principle*." This statement in no way denies that maintaining our existence necessitates killing living beings. Another key premise is that the human potential for caring is not static or limited—it can be both extended and deepened. The ecological crisis is embedded in an ecocultural crisis. Its resolution will necessitate cooperation and collaboration among the peace, social justice, and ecology movements.

Naess does not see himself as "inventing" deep ecology. Rather, he gave a name and a philosophical framework to a minority tradition, a nascent social movement that has been with humanity since at least Buddha, Chuang Tzu, Saint Francis of Assisi, Thoreau, John Muir, and Aldo Leopold, and is epitomized by Marjory Stoneman Douglas's 1947 *Everglades: River of Grass* and subsequent crusade to save the Everglades.²⁹ This movement finally came of age in the contemporary era after Rachel Carson's *Silent Spring*. Naess's work on "deep ecology" can be subdivided into three main thematic areas.³⁰

What I refer to as Naess's deep ecology approach (deep ecology as an ecophilosophical approach) represents his contributions to deep ecology theory—it is essentially an outline of a general philosophy of life, which draws considerable inspiration from Gandhi and Spinoza. The focal points are encouraging ultimate beliefs that support our capacity to identify with all living beings and Naess's general, pluralistic, normative systems-based strategy for assisting individuals in the process of weaving their ultimate beliefs, descriptive and prescriptive premises about the world, ecological science, and philosophy into systematic conceptual structures for relating to the world—ecologically inspired *total views* or *ecosophies*.

His work characterizing and supporting deep ecology as an international, grassroots social and political movement, along with his work enter-

SERIES EDITOR'S INTRODUCTION

ing into the fray, addressing conflicts, implications, and practical applications of the theory, falls into the realm of contributions to the “deep ecology movement.” Supporters of the deep ecology movement are not united by a commitment to deep ecology as an academic ecophilosophy (which they may not be familiar with or embrace), but by their willingness to endorse the eight-point deep ecology platform, prepared by Naess and Sessions in 1984.³¹ Finally, work discussing his personal systematization of a deep ecological total view falls into the realm of “Ecosophy T.”

Naess coined the terms *deep ecology* and *shallow ecology* in 1972 to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis. In proposing the deep/shallow contrast, he made a technical semantic distinction directed at our level of problematizing—the extent to which we can, and do, coherently and consistently trace our views, practices, and actions back to our ultimate beliefs or bedrock assumptions. Naess starts with a premise, which he has investigated empirically, that at the level of their ultimate beliefs, people generally identify with and appreciate nature. He then uses this to argue that many regrettable environmental decisions are made in a state of “philosophical stupor,” in which narrow concerns are confused with, and then substituted for, more fundamental ones.

The “shallow,” currently more influential approach to environmentalism is identified with treating the symptoms of the ecological crisis, such as pollution and resource degradation. This reform-oriented approach is grounded in technological optimism, economic growth, and scientific management, not in ultimate premises that plumb the relationship between people and nature. It thus ultimately fails to address the philosophical, social, and political roots of the ecocultural crisis.

The “deep” approach, on the other hand, while in no way discounting the exigency of addressing pollution and resource degradation, adopts a broader, long-term, more sceptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach’s proposed solutions take into consideration the nature of reality and the complexity of the problems its adherents hope to rectify. Stressing the importance of addressing the fundamental roots and coevolving causes of the ecological crisis, deep ecology posits that along with humans’ special capacities for reason and moral consciousness come special responsibilities,

particularly in relation to the flourishing of nonhuman life and the ecocultural sustainability of the planet.

The deep ecology approach calls for expanding our sphere of concern to all living beings—charismatic or dull, gargantuan or tiny, sentient or not. It acknowledges that every living being has value in itself and views the flourishing of nature and culture as fundamentally intertwined—as part of one reality. This *wide-identification* is characterized by the perception that all life is interdependent; common goals bind all living beings to the life process. In Naess's view one can arrive at wide-identification by drawing on a broad diversity of philosophical or religious ultimate premises, with roots ranging from Christian Stewardship to the Gaia Hypothesis to Naess's own ontologically inspired "Self-realization!" In its most expansive form, wide-identification is the intuition that nature's interests and our own coincide, as with Naess's "Self-realization!"—something akin to a blending of the Hindu *ātman* with a biospherical Pareto-optimality principle. Simply stated, this principle asserts that the increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other individuals or species.

By juxtaposing these two, almost caricatured perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The central premise is that society's potential to overcome the ecological crisis rests on guiding discussion and debate to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and their actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an individual's actions and his or her fundamental beliefs, while possibly engendering serious ancillary conflict along the way, will ultimately generate progress toward ecocultural sustainability.

Naess contends, as I have pointed out earlier, that humans act as if we have total views whether or not we make such structures explicit. Because our decisions regarding society and nature are guided by our total views, Naess maintains, we *should* attempt to articulate them. By making these structures explicit, we expand both our opportunities for fruitful debate and

SERIES EDITOR'S INTRODUCTION

interchange and our possibilities for creating policies that are consistent with our collective ultimate beliefs. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending "rights" to certain nonhuman life-forms or grading intrinsic value. The ontologically inspired deep ecology approach attempts to counter the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudo-rational thinking.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of "depth." In the context of deep ecology as an ecophilosophical approach, depth refers to both the general level of problematizing we employ in seeking out the underlying, co-evolving causes of the ecocultural crisis and the extent of our willingness to consider an expansive array of social and policy responses, even if they necessitate changes that constitute a radical departure from the status quo. Rather than calling for a new environmental ethic or a radical change in fundamental values, Naess's approach to ecophilosophy centers on transforming practice and policy by challenging us to develop more thoroughly reasoned, consistent, and ecologically inspired total views. This work represents a culmination of his effort to integrate reason and emotion. He has created the foundation for a new and promising human/nature relationship that positions humans as plain citizens with special abilities and unique responsibilities and nature as mentor, measure, and partner rather than servant. The current state of global ecological unsustainability has made Naess state that he is optimistic about the twenty-second century but pessimistic about the twenty-first; humans have a long way to go.

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of being inherently fascist, antihumanist, antifeminist, and against having indigenous peoples share wilderness areas with nonhuman life-forms.³² As the articles in volume X will show, none of these criticisms are compatible with a sophisticated reading of Naess's writings on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has clear answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three

key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not, on first principles, embrace wide-identification? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that lead to long-term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable means? Third, how can deep ecology help resolve conflicts in environmental decision making when those conflicts result not from pseudorational thinking but from genuine value conflicts?

Throughout this essay, I have tried to show how Naess's life of rich and varied spontaneous experiences and internal tensions have shaped not only who he is as a person, but also who he is as a philosopher. Viewed separately, Naess's contributions to academic philosophy, social research, and ecological philosophy and activism can appear discordant, dilettantish, and incoherent. When, through careful study of his helical progression, his philosophical and personal maturation, the pattern of the whole unexpectedly reveals itself as a unity, the whole suddenly becomes much more than the simple sum of individual books and articles. With the distance of a meta-perspective, Naess's collective philosophical contributions can be seen as a mosaic—as a superordinate gestalt, in some sense, as a rich and inspiring, but inevitably fragmentary total view. Naess has breathed life back into the study of philosophy by turning its study back to life. With his cultivation of a meta-perspective, a whole, new (old) approach to philosophy and way of seeing the world emerges. This richly patterned mosaic, by encouraging us to celebrate our freedom and affirm life, can help us to reshape our relationship to each other and the Earth in new and promising ways.

Conclusion

It was only as a professor that I became aware of the difficulties of suppressing the significance of the development of feelings in human affairs while at the same time worshipping reason. Both are constantly needed.

Arne Naess, *Life's Philosophy*

The ten volumes of this series (along with a subsequent volume of conversations between Naess and myself on deep ecology and his philosophy)

SERIES EDITOR'S INTRODUCTION

make available for the first time access to the breadth and depth of Naess's philosophical thought. Efforts to judge the significance of Naess's philosophical oeuvre—assertions made in the first sentence of this essay—can now be taken up on an informed basis. When embarking on this process, it may prove beneficial to reflect on Henry Adams's insight on the fundamental limitations of communication, and especially the limits of communicating one's fragmentary total view, "No one means all he says, and yet very few say all they mean, for words are slippery and thought is viscous."³³ Spinoza ends the *Ethics* with the following remark: *Sed omnia praeclara tam difficilia, quam rara sunt* ("But all very clear things are as difficult as rare").

In *The Radical Spinoza*, Wienpahl translates the phrase more literally than usual, rendering *praeclara* as "very clear" rather than the typical "excellent."³⁴ The quest for clarity is painful and difficult as well as amaranthine. The alternative, however, is to abandon joy and freedom and thus meaning. This is the essence of Naess's distinction between being an *academic philosopher* and being a *philosopher of life*, between merely *functioning* and *living*. Drawing inspiration from Spinoza, Naess has cultivated a practice of both integrating reason and emotion *and* transforming negative emotions into positive ones. His challenge is before us and the frontier is long—the choice, however, is ours.

Editorial Approach

Naess has always written books as if they were exercises for himself, tentative formulations that chronicled his views at that very second but were always subject to change. As I indicated previously, many of the prior editions of his books were poorly edited and sparsely documented. Existing bibliographies were incomplete, and indexes (in the rare cases in which they existed) were always inadequate. Quotations were often transcribed incorrectly and ill-referenced. In addition, the breadth of his work was enormous and sometimes repetitive. Arriving at a plan for a representative *Selected Works* that would have a consistent format and design was no easy task.

All the selections for the *Selected Works* were made in close consultation with Naess. I would prepare recommendations from my master bibliography file and then, whenever we disagreed, we would discuss the pros and cons of the piece and whether it was appropriate for inclusion (this ap-

proach proved particularly helpful when we reached the *Selected Papers* volumes). We immediately made a decision to exclude works that were widely available and currently in print. Other important works, such as his dissertation, and his major work on lay people's conception of truth, his work on the semantics of democracy and ideological controversy, and his contributions to history of philosophy were more difficult to exclude, but the nature of the project as a selected works demanded such tough choices. I was encouraged by the fact that Naess often published articles that summarized or updated earlier works. In the end, I was able to reflect a significant portion of the ideas and concepts in these excluded works by including articles of that type in one of the three *Selected Papers* volumes.

The details of editing proved more complex. Much to my chagrin, I very humbly learned how much work goes into a project of this scale and complexity. We decided early on that the level of editing required to bring the prior publications up to the high standards of contemporary academic philosophical publishing would necessitate revised editions. We also decided that since we were preparing revised editions and Naess was alive and could review the work, we would make the role of the editor invisible and not include tedious footnotes chronicling all the changes, however significant they might be. The historical significance, intricacy, and sheer magnitude of *Interpretation and Preciseness* (SWAN I) warranted special consideration. For these reasons, we decided that it would be best to prepare only an edited version for this volume and not attempt a complete revision as with the other volumes. In the early stages of the project Naess and I worked together closely, intimately. In my effort to eliminate errors and to enhance readability, flow, and clarity of argument, I brought Naess question after tedious question when I first embarked on the project (particularly when I was in Norway as a Fulbright Scholar in 1996). After working through several manuscripts, Naess decided to place the remainder of the responsibility for revising and editing the manuscripts in my hands.

We have made our best effort to reconcile inconsistencies, make corrections, and chase down incomplete bibliographic references (in most cases no bibliographies existed for the original works). I regret, however, that some imperfections remain. I am also responsible for any new errors that have been introduced—their existence, unfortunately, is unavoidable. I am, however, heartened by a conversation I had with Naess midway through the project, after he had reviewed several drafts of revised manu-

SERIES EDITOR'S INTRODUCTION

scripts. He commented that at least 90 percent of my revisions resulted in improvement and that no significant misinterpretations had been introduced. Given the nature and complexity of this project, that sounded like odds I could live with.

Acknowledgments

A project of this magnitude, by its very nature, represents the labor and love of an entire community. It could never have gotten off the ground, much less been completed, without a fantastic and deeply committed team. I have been blessed by the opportunity to work with, learn from, and receive guidance and support from so many talented friends and colleagues. It's been a wild ride; I owe you all a tremendous debt of gratitude.

First, the inspiration for the *Selected Works* and the majority of its financial support are due to the foresight and generosity of "Miracle Doug," Douglas Tompkins, president of the Foundation for Deep Ecology (FDE). Thanks for your vision, Doug. Quincey Tompkins Imhoff, former executive director of the Foundation (and current vice president of the board), also deserves recognition for her tremendous support during the early years of the project, as do program directors Jerry Mander and John Davis. Special thanks also go to Sharon Donovan, the Foundation's publishing manager, who in the project's final years has guided it through a long and sometimes circuitous path to completion. The Foundation has also always had an amazingly gifted and dedicated staff. At one point or another, many of its staff had a hand in helping this project along—offering assistance at a key point, a kind word, inspiration, or simply good cheer and a smile. Thank you, Denise Wilson, Debi Barker, Esther Li, Lizzie Udwin, Julie Lindow, Miyo Sakashita, and Emily Lydgate.

I was also supported by the Fulbright Foundation with a senior research/teaching fellowship at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. Additional support came from Western Michigan University. Special thanks go to WMU's dean of the College of Arts and Sciences, Leonard Ginsberg, and to my chair, Thomas Bailey. My colleagues at Western Michigan University also deserve thanks for their tolerance and succor while I focused all my available energies on this project. I am grateful for their flexibility and generous support. Wil Emmert, one of WMU's Research and

SERIES EDITOR'S INTRODUCTION

Program officers, also deserves a great thanks for his patience and skillful assistance.

The project has been blessed with a distinguished advisory board—Robert S. Cohen, Bill Devall, Alan Drengson, Ingemund Gullvåg (deceased), Per Ingvar Haukeland, Kit-Fai Naess, Nicolas Rescher, George Sessions, Michael Soulé, Douglas Tompkins, and Jon Wetleson. All of the advisers offered significant assistance in one form or another. Bob Cohen graciously shared his expertise and offered invaluable advice, encouragement, and support throughout the project. Bill Devall gave encouragement and helped bring volume X to completion by coauthoring its preface. George Sessions offered advice on the selections for volume X, provided guidance, and carefully reviewed a draft of this introduction. His suggestions greatly improved its flow and clarity. Kit-Fai Naess's tremendous moral support and great assistance in locating obscure documents and preparing bibliographies were invaluable.

Alan Drengson's contribution as a project adviser and in the project's final year as Associate Editor deserves special mention. At a crucial time, when the project was stalled in its later stages, Alan stepped up to the plate and played a key role in helping shepherd the project to completion. In particular, he took over most of the day-to-day project-coordination responsibilities for the final year of the project. He reviewed the copyedited manuscripts for volumes I, VIII, IX, and X, oversaw preparation of the author's prefaces to each volume and the editors' prefaces to volumes VIII, IX, and X, and reviewed the final manuscript proofs. This was not an easy task. I owe Alan a great debt for his fortitude, commitment, and generosity. For his contribution to the difficult and taxing responsibility of overseeing the final preparation of volume I, he has been credited as its sole editor.

I am lucky to have been supported by two astonishingly capable, committed, and patient project assistants. Kim Zetter played a critical role in getting the project off the ground and keeping it on schedule for the first three years. Later, Barbara Pijan helped steer the project back on track and over some awkward obstacles after it had run off course. Their talent and dedication played a major role in bringing to life the books before you. Thank you, Kim and Barbara, for your stalwart devotion to the project.

The beautiful and elegant design of the series is the work of Tomatsu Yagi and his nephew Akira Yagi. Ralph Fowler played a significant role in executing the Yagis' design and by filling in any missing gaps. Ralph also

SERIES EDITOR'S INTRODUCTION

performed the typesetting for volumes II–VII. The skillful and efficient crew at BookMatters performed the remainder of the typesetting. Katherine Silver handled the Brobdingnagian task of project management on volumes I and VIII–X and the last crucial stages of the project with aplomb, attention to detail, and fortitude.

The bulk of the project's copyediting was performed by the meticulous and supertalented Anne C. Collins, Ph.D., copyeditor extraordinaire. Additional copyediting was provided by Mary Anne Stewart and Kathy Walker. Indexing was performed by the immensely competent Nancy Mulvaney of Bayside Indexing Service, Julie Shawvan, and Leonard S. Rosenbaum. Proofreading was provided by Carrie Pickett.

Ingemund Gullvåg translated *Which World Is the Real One?* Iver Ørstavik provided the translation of "Experts' views on the inherent value of nature." The original editions of Naess's texts were keyed or scanned by the able and efficient crew at AgAccess—David Katz, Karen van Eppen, Jacob Katz, Rachna Boon, and Tim Rice. Additional keying of articles for the *Selected Papers* volumes was provided by Nancy Ropecka and Jane Drengson. Barbara Pijan, d Jones, Tony Hainault, and Debbie Reid deserve thanks for their careful and thorough transcribing of more than thirty-five hours of discussions with Arne Naess. Thanks are also owed to Tim Quick for his help with bibliographic research for volumes I and VIII–X, and to Kelly McKernan for assisting Alan with photocopying and faxing. In addition, a special thanks goes to Robert P. Goldman, Sarah Kailath Professor of Sanskrit and Indian Studies at the University of California Berkeley, for generously and graciously offering assistance on contemporary Sanskrit and Hindi terms.

I am grateful to the dedicated and very patient staff at Kluwer Academic Publishing. I am sad that our original editor, the immensely talented Annie Kuipers, who first recognized the importance of this project, did not live to see it come to print. Stephanie Harmon, Annie's replacement, worked closely with me on editorial matters and on finding high-quality recycled paper, cloth, foil, and other materials that meet the strict environmental considerations of FDE. In the final five years, the able and gifted Charles Erkelens was our editor.

Additional advice and moral support were provided by colleagues, friends, and family: Aimee Carroll, Kirsten Coyne, Paul Craig, Neal Goodwin, Byron Hahn, Ladislav Hanka, Alastair Hannay, Anna Leidberg-

SERIES EDITOR'S INTRODUCTION

Miron, Danny Moses, Richard Norgaard, Max Oelschlaeger, Brian Recht, Stephanie Sarvar, Ed Saxon, Geir Michael Sommerhein, Petter Sorum, and Kristin Walstad. Thanks for your efforts to coax me out of the cave.

Special thanks go to d and Reuben for their forbearance and succor. Someday, all too soon, Reuben will recognize that the invisible “work fairies” that were constantly pulling me back to my office don’t actually exist. I can’t wait.

Most of all, thanks to Arne Naess for placing his trust in me—it’s been a gift, something like an extended trudge up to Tvergastein, but without the fresh air and perspective. Taking on this project has been somewhat like receiving Pandora’s box as a present—all sorts of ills and plagues reared their heads along the way. I often felt that I was on a never-ending climbing descent in the night. I was always wondering about rappelling off my rope into the abyss.

The SWAN has taken flight, and I have landed on firm ground—I think? In all seriousness, I learned invaluable lessons. The more I worked through Arne’s writings, the more open-minded and optimistic I became. I found myself cultivating perspective and looking at the problems and challenges before me with fresh insights. I also found myself responding with more grace and equanimity in my efforts to counteract the numbing effects of contemporary society.

It is strange and ironic, however, that in being the series editor for the *Selected Works* of the father of deep ecology I spent so much time inside, chained to a desk. But this is part of the paradox of working with Arne Naess. I am reminded of one of my favorite poems—Gary Snyder’s “Axe Handles.” The last few lines read:

Pound was an Axe,
Chen was an axe, I am an axe,
And my son a handle, soon
To be shaping again, model
And tool, craft of culture,
How we go on.

And then it makes sense.

Harold Glasser
2004

Notes

1. In writing this essay, I found myself drawing on more than twelve years of friendship with Arne Naess. A simple bibliography could not do justice to describing how this subtle and multilayered gestalt has been formed. My perception of Naess and his work has been shaped by more than thirty-five hours of transcribed conversations between us, countless other conversations, letters, scraps of paper, e-mails, and Arne's copious annotations in my own books and articles. Camping trips, bouldering, hikes, and cross-country skis have also helped inform my understanding of Arne Naess the fiercely competitive, playful, elfin trickster, who springs to life in nature. I have benefited from three extended visits to Norway, including a Senior Fulbright at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. I have also spent other stimulating periods of time with Arne in Svalbaard, England, California, and the deserts of Arizona and Nevada. Finally, and probably most important, I have been inspired and forever changed by my own reading and editing of his work. In this regard, both previously published and unpublished materials have been influential in forming my own perspective on Arne Naess the philosopher. One key published source has been Naess's "How my philosophy seemed to develop," in *Philosophers on Their Own Work*, edited by Andre Mercier and Maja Svilar (Bern: Peter Lang, 1983), pp. 209–26 (in SWAN IX). Another source for insightful material on Naess and A. J. Ayer (as well as six of their contemporaries) is a book created from debates by philosophers for Dutch National Television. See, especially, "The glass is on the table: An empiricist versus a total view," in *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), pp. 11–68 (in SWAN VIII). Finally, additional perspective was offered by an article that discusses Norwegian philosophy from the end of the Second World War to just before 1980: Arne Naess and Jon Hellesnes, "Norway," in *Handbook of World Philosophy Since 1945*, edited by John Burr (Westport, CT: Greenwood Press, 1980), pp. 159–71.

On some of the fine points of this essay, I have benefited from extended conversations with my colleague and old friend George Sessions. I have also profited, over the years, from the significant literature that has been created to shed light on Arne's life and work. Many of the ideas and thoughts introduced in this essay—drawn from my own firsthand experiences with Arne—can also be found in these sources. In many cases, issues only touched on here are taken up in much more detail in those sources. Five key references for historical material on Naess and the evolution of his philosophical approach are identified below (two of which are videos). A wealth of additional material is available in the five festschrifts for Naess (see details in note 15 below). The

SERIES EDITOR'S INTRODUCTION

first of the festschrifts, *In Sceptical Wonder: Inquiries into the Philosophy of Arne Naess on the Occasion of His Seventieth Birthday*, edited by Ingemund Gullvåg and Jon Wetlesen (Oslo: Universitetsforlaget, 1982), contains the most thoroughgoing analyses and critiques of Naess's earlier philosophy that I am aware of, and many of the articles have insightful responses by Naess.

Books

Warwick Fox, *Toward a Transpersonal Ecology: Developing New Foundations for Environmentalism* (Boston and London: Shambhala, 1990). See, especially, chapter 4, "Arne Naess and the Meanings of Deep Ecology."

Ola A. Hegdal and Tore Strand Olsen (illustrator), *Jeg, Arne Naess: Et Tegnet Liv* (Arne Naess: A cartoon story of my life) (Oslo: Kagge Forlag, 2001). A unique and insightful look at Arne's life, based on an idea from Arne's wife, Kit-Fai.

16. Arne Naess, *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre*, translated by Alastair Hannay (Chicago: University of Chicago Press, 1968). In the 1970s, philosophy was still influenced by the events of the Second World War. Heidegger's flirtation with National Socialism and the Hitler regime, and his unusual way of expressing himself, made it difficult for him to be considered a great philosopher. Naess's book on four contemporary

SERIES EDITOR'S INTRODUCTION

philosophers was seen as unique because he interpreted in a scholarly and positive way both Heidegger and the fiercely anti-Heideggerian philosopher Rudolph Carnap, a logical empiricist. Carnap, who was forced to flee Nazi Germany, could not fathom how Naess, as an old friend, could present positive discussions of Heidegger and himself in the same book. The other two philosophers included in the book, Wittgenstein and Sartre, also held completely incompatible views of philosophy, but Naess accorded them equally high positive appreciation.

17. For example, works by Naess that are still in print, such as *Ecology, Community, and Lifestyle: Outline of an Ecosophy*, translated and edited by David Rothenberg (Cambridge: The University Press, 1989), and *Life's Philosophy* (2002; see note 2), were not included, for obvious reasons.
18. In "How my philosophy seemed to develop," p. 215, Naess mentions the particularly strong impression, the magnificent expansion of his own "life's frame of reference," made by H. G. Wells's early popularization of the history of life, *Outline of History* (New York: Macmillan, 1920).
19. For detailed discussions of Naess's assessment of logical empiricism, see Arne Naess, "How can the empirical movement be promoted today? A discussion of the empiricism of Otto Neurath and Rudolph Carnap," in *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. Vandormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), pp. 107–55 (in SWAN VIII). (The original German version of Naess's article, "Wie Fördert Man Heute die Empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolph Carnap," was written during 1937–39.) For Naess's experiences attending the Schlick seminar, see Arne Naess, "Logical empiricism and the uniqueness of the Schlick seminar: A personal experience with consequences," in *Scientific Philosophy*, edited by Friedrich Stadler (Dordrecht: Kluwer Academic, 1993), pp. 11–25 (in SWAN VIII).

Schilpp (Chicago: Northwestern University Press, 1939), p. 597, as quoted in Wallace I. Matson, *A New History of Philosophy*, vol. 2 (San Diego: Harcourt Brace Jovanovich, 1987), p. 454.
23. Naess, "How my philosophy seemed to develop," p. 223. For more details, see Richard McKeon and Stein Rokkan, eds., *Democracy in a World of Tensions* (Chicago: University of Chicago Press, 1951). Naess, as the scientific leader of the project, was viewed as a UNESCO administrator; he was only credited as

SERIES EDITOR'S INTRODUCTION

- being the author of the questionnaire itself and the summary paper, although he was intimately involved with the project at all levels.
24. Naess went on to perform a reconnaissance of Tirich Mir (25,263 feet) in the Hindu Kush in the summer of 1949. He then led the successful Norwegian first-ascent team in 1950. The expedition, which included botanical and geological assessments of the region, is chronicled by the team members in Naess et al., *Tirich Mir: The Norwegian Himalaya Expedition*, translated by Sölvi and Richard Bateson (London: Hodder and Stoughton, 1952). Naess successfully pursued a second, vastly more technical expedition to Tirich Mir in 1964. His "The south wall of Tirich Mir East," *Himalayan Journal* 26 (1965): 97–106, discusses this expedition and includes interesting commentary on expedition philosophy and climbing ethics. The article appears in SWAN X, along with other papers on Naess's relationship to mountains and views on mountaineering.
 25. Arne Naess, "Reconnaissance, 1949," in *Tirich Mir*, p. 22.

ogy approach to ecophilosophy," the "deep ecology movement," and Naess's "Ecosophy T" (a particular deep ecological total view), see Harold Glasser, "Deep ecology," in *International Encyclopedia of Social and Behavioral Sciences*, edited by Neil J. Smelser and Paul B. Bates (Oxford: Pergamon, 2001), pp. 4041–45. For a detailed discussion of deep ecology as an ecophilosophical approach with special attention to its policy implications and a discussion of deep ecology's relationship to Naess's earlier philosophical work, see Harold Glasser, "Naess's deep ecology approach and environmental policy," *Inquiry* 39 (1996): 157–87 (reprinted in Witoszek and Brennan's *Philosophical Dialogues*).

31. For anthologies on the deep ecology movement, which include articles by Naess and other deep ecology supporters, see George Sessions, ed., *Deep Ecology for the Twenty-First Century* (Boston: Shambhala, 1995), and Alan Drengson and Yuichi Inoue, eds., *The Deep Ecology Movement: An Introductory Anthology* (Berkeley, CA: North Atlantic Books, 1995).
32. Naess rarely responds directly and definitively to these criticisms—this is not his nature. Siri Naess, however, made an interesting effort to explore the potential of using Naess's Ecosophy T as an inspiration for a feminist normative system in her "Self-realization," in *In Sceptical Wonder*, pp. 270–81. She concluded that while Ecosophy T and her System F have much in common, Ecosophy T goes further by extending to all living beings its concern for activeness and creativity in relation to problems, egalitarianism, and support of the suppressed and exploited.

Author's Introduction to the Series

At ninety-two it is a great honor to be still alive and to witness the publication of my selected works in English. Few philosophers have their work published in a series, fewer still receive this honor before they die. When I was originally approached with the idea of publishing my complete works, I was overwhelmed and overjoyed, but added that not all my books and articles were important enough to merit such an honor. Selected works? Yes, and I am extremely grateful for this initiative and the final result, which presents a representative selection of my work from the earliest to the most recent. [*The Selected Works of Arne Naess* are hereafter referred to as SWAN.]

My interest in philosophy began with Spinoza's *Ethics*, which as a seventeen-year-old I was fortunate to read in Latin. I appreciated Spinoza's grand vision and trusted him implicitly as a person. I accepted that human beings could, and should, have a general outlook with the grandeur of Spinoza's, but I recognized that our individual views on this grand scale will not be identical. Through the years I have realized that there is a splendid variety of interpretations of Spinoza (SWAN VI and IX). His texts are exceptionally rich. As the years have gone on, I have focused on how he leads us to realize we can increase our freedom and sense of connection with the world through strengthening and intensifying our *positive* emotions. For example, loving and caring for our place and others leads to an expansive sense of being part of a much larger world. Emphasizing hatred and anger, on the other hand, makes us feel smaller and isolated from the world. Spinoza, as I interpret him, would express this by saying that "We are as large as our love." Increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow.

Before I left gymnasium [the end of secondary education] the headmaster asked me, "What do you intend to be?" My immediate answer was "A philosopher." In fact, I had already conceived of myself as one. I viewed the

AUTHOR'S INTRODUCTION TO THE SERIES

writings of many contemporary philosophers that I was familiar with, however, as vague and airy and certainly not as inspiring as Spinoza.

My doctoral thesis in philosophy of science was an effort to remind us that in science the content of a theory is not independent of research behavior—the activities of observing, confirming, disconfirming, and so on, and that these are set within a deep context of place, history, and culture. Later, as a postdoctoral researcher at the University of California at Berkeley, I studied the behavior of experimental psychologists doing animal research.

In 1934 and 1935 I studied in Vienna and while there became a member of the famous Schlick seminar, the main discussion group of the Vienna Circle. Their quest for clarity and cordial cooperation in pursuit of knowledge led me to appreciate that “What do I mean?” is an open question. I concluded that we never intend to express anything extremely definite, even in mathematics or symbolic logic. I saw the importance of using empirical methods to find out how we actually use certain expressions and sentences. I developed and applied a wide variety of such methods, which became part of the core for the empirical semantics that runs through my work. I continued to do this type of research into the 1990s, my last project being one in which I questioned experts and policy makers about their ideas of values intrinsic to the natural world (in SWAN X).

In one of my earlier studies, I reviewed about 700 articles from philosophers concerning their use of the word *truth*. For the most part, I found these unconvincing and soon started on empirical studies of the use of *truth* among ordinary nonprofessional people and schoolchildren (in SWAN VIII). Many philosophers seemed to assume that ordinary people hold very naive views about these deep matters. I found through research that, on the contrary, the views articulated by these “ordinary” people were every bit as sophisticated as those held by professional philosophers. This reinforced my conviction that, generally, we greatly underestimate ourselves. Much academic philosophy was narrowly focused and abstract. Philosophers who elicited interest in wide-ranging issues of practical and global importance, such as nonviolence and social justice, have in my lifetime said things that were considered creative, but often too far out. In spite of consistent proclamations that science neither would nor could take over all the problems discussed by philosophers, I tried to argue in ways that reminded readers of science done as open inquiry, and I tried to emphasize that it is occasionally

AUTHOR'S INTRODUCTION TO THE SERIES

necessary to perform empirical research to illuminate or support a philosophical viewpoint.

My empirical and historical research led me to realize that there are no certainties and that there is a great diversity in our spontaneous experience as well as endless ways to describe and appreciate the complexities and values of the world. Thus, I realized that I am one of those lifetime seekers that the ancient Greeks called a *zetetic* (see SWAN II and VIII). From my research on scepticism and the foundations of science and logic, it became clear to me that pluralism (every event has many descriptions and possible outcomes), possibilism (anything can happen), and a healthy scepticism (always seeking the truth but never claiming it) make up the most consistent approach to respecting the perspectives and experiences of others, human and nonhuman.

From my empirical studies of semantics, and from my knowledge of several languages, I came to appreciate the complexity of communication. Being committed to Gandhian nonviolent communication, I saw the importance of avoiding dogmatism and fanaticism. One of the most important discoveries coming from this research, leading to the publication of my major book, *Interpretation and Preciseness* (SWAN I), was the insight that we cannot avoid values in any field of endeavor or research. There are no value-free inquiries or theories. Even if we refuse to express our values, this is itself an expression and choice of values. We must, therefore, be clear about our value choices and try to make them explicit. The choices we make, as Spinoza pointed out, shape the quality of our lives, and values emphasizing positive emotions or feelings are expansive and lead to our growth. We must become ever more aware of our choices and the values involved. Even pure logic assumes certain norms. Empirical research can shed light on these matters. My colleagues in philosophy often found my empirical work perplexing. I, in turn, grew to underrate the necessity of visiting great centers of philosophy, as I preferred to be close to or in the mountains.

When I visited the United States, it was mostly to climb in the mountains or walk and camp in the desert. On one fortunate visit, I dropped in at the graduate students' discussion room at Harvard. Speaking with students who were writing their doctoral theses in philosophy, I understood that my knowledge of contemporary philosophy, and of recent important contributions in its various fields, was narrowly limited to special themes of lively personal interest. Even in later years, the tendency to take personal inclina-

AUTHOR'S INTRODUCTION TO THE SERIES

tion very seriously colored my contribution to the philosophical literature. As can be seen, though, from the titles in these *Selected Works*, my strongly felt interests span a rich variety of fields, philosophical traditions, and movements.

Since childhood I have experienced an intense joy in being together with animals and plants and in contemplating the immense evolutionary development of life on earth over millions of years. From an early age I also developed an intense love for mountains and for being in them. Much of my creative philosophical work was done at Tvergastein, my mountain hut in Norway (see SWAN X). My devotion to outdoor life is in the Norwegian tradition called *friluftsliv* (literally, free-air-life). In many respects, I approached philosophical and cross-cultural studies as if I were a field ecologist or naturalist. It was against this background that my work from the 1960s onward focused with close attention on cultural diversity, biodiversity, sustainability, and the deep ecology movement.

My work since the Second World War has been increasingly within movements such as those furthering social justice, peace, and ecological responsibility. During the war, I engaged in anti-Nazi activism, and from that time also in promilitant Gandhianism, a nonviolence that is not pacifist in the usual sense but insists that if it is a bloody fight for justice against injustice, we seek "the center of the conflict" and, if necessary, cooperate with people who use arms. During the Cold War, I participated in the "third side," against both communism and extreme anticommunism, for example, as the scientific leader of a UNESCO project bringing Marxist and anti-Marxist politicians and political science researchers together in an unbiased discussion of the essence of democracy and freedom. Some of the relevant publications are included in SWAN IX.

The broad spectrum of books and articles included in the *Selected Works* represents, in many ways, a chronicle of my passions and influences. The *Selected Works* record, albeit in an inevitably fragmentary way, one possible expression of these. My dream and hope is that some readers will be inspired by their sheer variety, and that young philosophers will be encouraged to let strong personal motivations steer their studies.

Working habits vary. Some people write an article and go on to the next without looking back on the old one; others come back from time to time, radically revising and changing the old one. The latter is my way of working. Lecturing in many places about these subjects, I have found it

AUTHOR'S INTRODUCTION TO THE SERIES

natural to revise the old manuscripts until sometimes very little is left of the original. Therefore, I have always viewed my writing as preliminary; a year, five years, ten years after publication of the first editions I have itched to revise, *thoroughly* revise them. When my first book was printed in 1936, I went to watch the hulking presses printing out one page at a time. I was terrified, thinking of mistakes or some awkward sentences being duplicated again and again.

When I was offered the opportunity to have a selected-works series published, I immediately thought I would like to review all my work and ask how, from today's perspective, I might answer the difficult questions I had earlier attempted to probe. Such a task would have been a particularly difficult proposition, because although many of my books and articles contain new ideas, the ideas are often not developed as well as I might have hoped. But alas, I am saved—at my age there is not time for me to accomplish such a comprehensive reevaluation of my work; I do not even have the capacity to do it now in any case.

Who could contemplate undertaking a publishing project of such ambitious proportions? Douglas Tompkins, mountaineer, entrepreneur, protector of wilderness in Chile and Argentina, and creator of the Foundation for Deep Ecology, is such a person. "Miracle Doug," as I call him, likes the idea that the deep ecology slogans and the deep ecology approach were introduced by a philosopher. I am grateful to him for his firm conviction, inspiration, and great generosity. My gratitude, however, extends well beyond my thanks to Doug, to others who have supported and championed this project.

Quincey Imhoff, when executive director of the Foundation for Deep Ecology, supported SWAN with generous grants and other contributions. SWAN has also benefited from faithful assistance and cooperation in the preparation and editing of the manuscripts. The late Professor Ingemund Gullvåg prepared the initial translation of *Which World Is the Real One?* (SWAN III). Professor Alastair Hannay translated the first edition of *Communication and Argument* (SWAN VII) and offered invaluable suggestions for improving the readability of the first editions of *Scepticism* (SWAN II), *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), and *Gandhi and Group Conflict* (SWAN V).

Most of all, however, I am grateful to Harold Glasser, the series editor, and his assistant, Kim Zetter, who oversaw all aspects of the project from design to production. Glasser's unique combination of intellectual tenacity,

AUTHOR'S INTRODUCTION TO THE SERIES

attention to detail, mastery of my work, and cooperative spirit made him a natural to take on the monumental task of selecting and editing my works. Glasser not only labored to improve the English and clarity of each manuscript, but his keen ability to ferret out countless technical and pedagogical errors has resulted in substantial new editions of volumes II–VII that are both far more comprehensible and accessible than the originals. I thank him for his valiant work on this project, both during his stay in Norway as a visiting Fulbright professor, where we collaborated on a strategy for revising the previously existing material, and in the subsequent years it has taken to complete the project.

From the beginning of the SWAN Project in 1994, Alan Drengson has encouraged and helped to move this work forward in numerous ways. Especially in the last crucial stages of completing volumes I, VIII, IX, and X, his help and editorial oversight have been invaluable. Thanks for his devotion, good humor, and positive enthusiasm. Thanks to both Drengson and Tim Quick for their extensive bibliographic research. Thanks to Bill Devall for his support and encouragement and especially his help on the completion of volume X, *Deep Ecology of Wisdom*. Thanks to Anne Collins for her outstanding work as the copyeditor of the SWAN volumes. Thanks to George Sessions for his support and encouragement.

Last, but certainly not least, immeasurable thanks go to my wife, Kit-Fai Naess, who has worked beside me throughout the years to provide invaluable assistance, encouragement, and inspiration.

Arne Naess

2004

Author's Preface to This Edition

This work has the long title, *Freedom, Emotion and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics*. *Self-subsistence* is meant in the philosophical sense of “persistence of the Self,” not mere survival. *Emotion* refers to Spinoza's important view that strong positive emotion is necessary to make rapid progress to high levels of human freedom. The application of this view underlies my belief in the indispensable function of Spinoza to supporters of the deep ecology movement. Their positive relation to life on earth is highly emotional. They are led to a positive appreciation for the vast interconnection of life-forms in a wide ecosystem through an emotional care for life-forms of all kinds. A neutral, factual description of this interconnectedness is not enough to move us to act. A cold assessment of the usefulness of certain life-forms does not mobilize a persistent fight against the destruction of species that is going on everywhere.

A book on Spinoza's philosophy generally appeals to people with a background in the humanities, not in analysis and symbolic logic. To the former this book on Spinoza looks formidable: it seems to be filled with formulas. Why use such formulas?

One reason is obvious. Spinoza's *Ethics* is a complex text. There are, for example, more than 270 sentences of the kind “By . . . I mean,” “. . . is the same as . . .,” and so on, where “. . .” may be entities of some kind, including words, more complex text units, or concepts. Those with a prodigious memory might keep the hundreds of important connections between these 270 entities ready in their minds. Most of us cannot do this, and understanding what we are entitled to call a Spinozan total view escapes us. Extremely simple formal logic notation can help us decisively to keep these interconnections clearly in mind.

Are they extremely simple? I thought so when writing this book: “Only a couple of hours study and you will appreciate the help of the sym-

AUTHOR'S PREFACE TO THIS EDITION

bols." It seems, however, that the feeling of simplicity owed to my very early experience. When I was seventeen, I found a reference to the three-volume *Principia Mathematica* by Bertrand Russell and Alfred North Whitehead. They were said to have derived mathematics from pure logic—pure thought, I imagined. It sounded romantic, but the three big blue volumes were formidable. What did I pretend? The first series of derivations was peculiarly easy. They did not skip any premises, whereas the proofs in my school mathematics text jumped along like a boy who had hurt his knee. I enjoyed the logical calculi, and as I was young it was easy to learn. Not so easy perhaps for mature humanists, most of whom dislike such formulas. Strong motivation is essential to master such symbols.

The logical structure of Spinoza's *Ethics* leaves many openings for a variety of interpretations of the content. Historical evidence rules out a lot of them as expressions of the strictly personal view of Spinoza, who lived in a period very different from ours in most ways. Within a framework made up of the essential parts of the *Ethics*, there are many possible interpretations. Moreover, Spinoza changed his views in many ways over his lifetime. I am interested in what he would have retained in later editions of the *Ethics*, if he had lived considerably longer.

The difference between the history of ideas and the philosophy of total views is particularly clear in the case of great systematizers such as Aristotle, Hobbes, and Spinoza. Spinoza scholars like John Yolton who focus on the ideas of young Spinoza interacting with others in a particular spiritual environment find my approach somewhat strange and ahistorical. I think Yolton's findings are of limited relevance to my efforts at reconstruction and the search for salvation. As an example of what a systematic approach might imply, let us look for a moment at the word *Deus* ("God") in Spinoza's text. It is carefully defined. This fact makes it possible to leave it out in a reconstructed text! The definiens is simply substituted for the definiendum. From the point of view of a historian, and especially a historian of ideas, such an omission borders on blasphemy. For the systematician, the history of ideas is an indispensable auxiliary discipline, but only one among other important disciplines, for example, Medieval Latin—as in the use of the term *causa*. These are only auxiliaries, however! My central question has been, How can the texts of Spinoza, together with my more or less intuitively based appreciation of his person and mission, help me in my search for truth? Perhaps some others could be helped in the same way, perhaps not.

AUTHOR'S PREFACE TO THIS EDITION

There is such a splendid variety of Spinoza interpretations. However, it is difficult to understand why no one has focused on his insight into how we can increase our freedom through strengthening and intensifying our positive emotions. Spinoza says increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow. So many interpretations tend to focus on his so-called determinism, the illusion of free will, our slavery under negative passions, and on human beings as tiny creatures in a vast universe without understandable goals, and yet it is claimed rational to believe in God.

Few interpretations try to use Spinoza's own way of exposition with propositions, proofs, and fundamental axioms and definitions. Because of the great number of closely intertwined concepts, some sort of "Euclidian" method of exposition might or might not be the most convenient and yet be the only way to get a proper survey of his system as expressed in the *Ethics*. In any case, this is what I have tried to do in an exposition of some basic features of his system. For those who have experience using simple logical symbols, this text will be easy reading, but for those who have no such experience, what is said using formulas is also expressed in English.

I am convinced that Spinoza's firmly integrated view of human life, and the way to live it, will in the future inspire more people than ever before. We need Spinoza as a source of inspiration, but of course we also need our personal interpretations. Mine is only one of many.

Arne Naess

2004

Author's Preface to the First Edition

Of the many friends of Spinoza among professional philosophers, very few specialize in his philosophy as a system. This seems to me to be a deplorable situation, since few philosophers, if any, have so much to offer us today.

Spinoza's system belongs to the seventeenth century. Its concepts and structure are very foreign to us. Interpretations that try to be as faithful as possible to all details are necessarily of immense complexity—practically unsurveyable. What follows is a reconstruction of some aspects of the system that to me are of central importance for the understanding of human nature.

I am grateful for the help received from colleagues and students.

Abbreviations

The following abbreviations are used in reference to text units of Spinoza's *Ethics*:

D	<i>Definitio</i>	definition
A	<i>Axioma</i>	axiom
P	<i>Propositio</i>	proposition
Dem	<i>Demonstratio</i>	proof
Cor	<i>Corollarium</i>	corollary
Sch	<i>Scholium</i>	note
E	<i>Explicatio</i>	explanation
Aff	<i>Affectus</i>	emotion, affect
App	<i>Appendix</i>	appendix

The references are standardized:

ID7	Definition 7 of part I
IIIP9Sch	Note to proposition 9 in part III
IIIAffD3	Definition 3 of the affects at the end of part III
VP42Dem	Proof of proposition 42 in part V

Introduction

Spinoza's terminology is very rich. Several hundred different words and expressions in his axioms, definitions, theorems, and proofs express together the basic framework of his all-embracing system. Some of these terms are fairly unproblematic in their use, but most are not. One may safely assume that many pairs or groups of terms have the same extension, but this would not prevent them from having widely different meanings in the sense of connotation or intention. Thus, "to be substance," "to be (completely) in itself," and "to be (completely) free" may have the same extension but have different connotations.

Most of the key terms in the *Ethics* have different shades of meaning in different contexts. The differences are obviously relevant to Spinoza's total field of conceptual discriminations, which is so vast that a set of relevant relations between terms runs into the thousands. A survey of such relations was compiled as a preliminary to this work.¹

From a narrow didactic undertaking—the survey of essential terminological relations—I was led to take up the task of partially reconstructing Spinoza's system using a terminology that in some connections may sound strange or far-fetched to some of his students. This is unavoidable, however, if Spinoza's thinking is to be used in our lives.

The reconstruction starts with a set of eighteen theorems concerning that which is in itself or in something else; that which is conceived through itself or by something else; that which does or does not require something else in order to exist; and that which does or does not require other conceptions in order to be conceived.

This beginning is rather abstract and may, I am afraid, bore some readers, but the distinction between "in (through) itself" (*in se*) and "in (through) something else" (*in alio*) occupies a fundamental position in Spinoza's system. The distinction can be called *ontological* insofar as it has to do with ways

INTRODUCTION

of existing or being and *epistemological* insofar as it has to do with ways of conceiving. To avoid misunderstanding, however, I have sometimes elected to use the more dynamic term *lambanological*, which comes from the Greek verb λαμβάνω (to grasp), as opposed to the static and platonic *epistemological*. To be active or to act and to understand cannot be systematically distinguished in the *Ethics*.

The translation of *conceptus* to *conception* rather than to *concept* is preferred to keep the modern discussion of concept, conceptualism, nominalism, and realism at a distance, and also to catch some of the dynamism implicit in the Spinozistic *conceptus*. I take *conceptus* and *conception* to be just a substantivation of *concipere* and *conceive*. No concepts *result* from the acts of conception.

In Spinoza's system, cognition has more to do with "causing," "consuming," "freeing," and "grasping" knowledge than with "possessing" it. The neologism *lambanological* will be given the general sense of "having to do with grasping." Conceiving, understanding, acting, and (human) causing will accordingly be classed as parts or aspects of a unitary process, grasping.

In what follows, we shall often class a statement by Spinoza as either ontological or lambanological. Some comments on the practical criterion may therefore be appropriate. The distinction between ontological and lambanological as applied to the text of Spinoza refers to certain differences well exemplified in the eight definitions of part I of the *Ethics*.

The first definition (ID1) includes two *definiens* phrases: "that, the essence of which involves existence" and "that, the nature of which cannot be conceived except as existent." The latter makes the definitorial delimitation of a cause of itself directly and explicitly dependent on the act of conceiving. The phrase and its meaning in the introduced terminology are lambanological. The former does not express any such dependency explicitly and directly. It nevertheless refers to something, an entity, an *on* (*ov*). Consequently, I call it ontological. Thus, the first definition has a combined ontological *and* lambanological *definiens*. In short, it is ontological-lambanological. When the same test is used, ID2 and ID3 are also classifiable as combined ontological-lambanological. According to ID4, perceptions of the intellect (substance-perceptions) contribute to the delimitation of "attribute." Actually, nothing else is referred to. The *definiens* is surely lambanological. Since, however, an attribute is said to be that which the intellect perceives, the attribute itself is not a perception or any other feature of cognition. So we might add the adjective *ontological*. ID5 also exhibits both

lambanological and ontological meanings. ID6 and ID7, on the other hand, do not refer directly and explicitly to any conception or perception. They are purely ontological. The last definition delimits eternity in terms of conceiving and falls into the lambanological-ontological class. Thus introduced, the distinction does not automatically furnish any general criterion for what belongs to ontology and what does not. It definitely does not parallel the Kantian distinction.

Regarding the classical question of ontological or epistemological primacy, it is characteristic of Spinoza that both ontology and epistemology enter at the very bottom or start of his system—if there can be a “start” of a system. His fundamental vision is somehow beyond that distinction, it seems. He permits himself to mix ontological and epistemological statements in his proofs. I shall try to do justice to the fundamental vision of unity by elaborating *equivalences* in a sense to be clarified later. In part I of the *Ethics*, the unity of vision is attested by a series of parallel ontological and lambanological propositions. For evidence of this, see especially ID1, ID3, ID5, ID8, IA4, IA7, IP2Dem, IP3, and IP3Dem.

Many distinctions, for example those between God and man, and substance and mode, are less fundamental in the sense that they already presuppose the dual distinction: in itself or in something else, conceived through itself or conceived through something else. The dual distinction, on the other hand, does not presuppose the distinctions traditionally taken to be fundamental in Spinoza’s system. The notion “conceived through itself,” for instance, does not presuppose the notion of substance, nor does the notion of “in itself” presuppose the notion of God.

It has been argued that the distinction between substance and mode cannot be less fundamental than the one between “in itself” and “in something else,” since the person who makes the distinction is already a mode when forming the latter distinction. The priority is rather the other way around, it is said. Against this, I would answer, first, that the same argument, if valid, also holds against taking the distinction between substance and mode as the more fundamental, since the person making the distinction is already something in something else. Second, the fundamentality of the distinction between “in itself” and “in something else” has to do with Spinoza’s ontological status as a mode—*all* his life.

Why does Spinoza not introduce “in itself” in terms of substance? Why doesn’t he write “By being in and being conceived through itself I under-

INTRODUCTION

stand being substance”? From this and a series of other definitions one might try to reverse his text. My answer is that this would involve not only a change of mode of exposition, but also an unwarranted change of priority in Spinoza’s thinking: he understands and contemplates substance, mode, God, attribute in part as that which is in itself or that which is in something else, and that which is conceived through itself or that which is conceived through something else—not the other way around. The terms *substance*, *attribute*, *God*, *mode*, and *Nature* are expendable in his system, but of course they were necessary on the seventeenth-century scene. Much is gained today in understanding Spinoza by breaking down the traditional domination of those terms in expositions of the structure of his thought.

By means of the third definition of part I (ID₃), we eliminate from the text the term *substance* whenever doing so facilitates understanding. The definition is worth quoting here because of the peculiar shift from ontological to lambanological terminology—a shift I shall make use of in the following pages: “By substance I understand that which is in itself and is conceived through itself: that is, that the conception of which does not require the conception of another thing, from which it must be formed.” The property of “being conceived” is completely on a par with “being.” Substance cannot be unconceived, by definition.

The fundamental dual distinction is expressly and directly made use of in the *definiens* formulations or the proofs in the many text units: ID₃, ID₅, IA₁, IA₂, IP₂Dem, and so on. Indirectly, the dual distinction enters all through the *Ethics*. It enters, for instance, into all propositions in part I using ID₃ and into the proofs referring to ID₃, that is, IP₁Dem, IP₂Dem, IP₄Dem, IP₅Dem, IP₆Dem₂, IP₁₀Dem, IP₁₅Dem, IP₁₈Dem, and IP₂₈Dem.

To the ontological axiom 1, “that which is, is either in itself or in something else,” corresponds “that which is, is conceived either through itself or through something else.” This latter lambanological proposition cannot be denied a place in the system in spite of its not being explicitly formulated in the *Ethics*. It occurs as number six in my initial set of eighteen propositions (I call it A6). It is my contention that hundreds of more or less important, so-far-unstated theorems cannot be denied their place in the system. They follow either directly or indirectly from definitions, axioms, propositions, or other central statements in the very core of the *Ethics*.

In reconstructions, the lambanological parallel to axiom 1 can be introduced as a separate axiom, or derived from axiom 1 and a proposition, defi-

dition, or axiom. There are a number of possibilities open. We shall not, however, take up problems concerning the status of the various propositions as parts of various reconstructions. Instead, we shall leave the subject, repeating that our sets of theorems do claim validity, but not any definite hierarchical place in the expositions or reconstructions of the system, axiomatic or otherwise.

Even the very small set *A* of theorems contains as many as fifteen different predicates of high systematic relevance. To facilitate the survey of the theorems and to remind us of their internal relations, the lower predicate calculus is used to symbolize them in the survey beginning on page 14. To do this requires only seven capital letters. The eighteen propositions are symbolized by means of abbreviated predicate expressions.

In chapter 1, the use of symbols is purely heuristic and has little bearing on our choice of theorems or their derivation. Those who are not familiar with the functional calculus, or dislike symbols in philosophical contexts, may ignore formulations using symbols. In any case, translations of symbolic expressions are always included in the text.

Some logicians have discussed the possibility of formalizing Spinoza's system. Such an undertaking, however, is doomed to be unsuccessful given the complexity of his texts. What I have done in the following chapters has little, if anything, to do with formalization of a doctrine. Only a small (but central) sector of relationships in the *Ethics* is expressed in symbols, and the sector is itself isolated from the rest by more or less arbitrary, but heuristically justifiable, delimitations. The sector expressed by means of symbols in what follows makes up scarcely more than 1 percent of the *Ethics*, even if we limit ourselves to its major conceptual structures. Chapter 2 introduces the notion "conceivability of the nonexistence of something." It is an important ingredient of the notions "essence involving existence" and "freedom." These notions are all linked to the fundamental dual distinction: that which cannot be conceived as nonexistent is nothing else than that which is in itself (and so on). In a set of twenty-one theorems (referred to as B1–B21), various internal relations and relations to the theorems of chapter 1 are clarified.

The basic relation in all this is extensional equivalence—symbolized by "ekv." The relata of extensional equivalence are whole sentences. In the following chapters we make extensive use of a less intimate relation, namely, that of mutual implication: "If *x* has the property *A*, then *x* has

INTRODUCTION

property *B*, and if *x* has property *B*, then *x* has property *A*.” “Ekv” implies mutual implication, but mutual implication does not imply “ekv.”

In terms of conditions, the presence of property *A* is a sufficient condition of the presence of property *B*, if *A* implies *B*. If something is in itself, this is, according to Spinoza, a sufficient condition of its being conceivable through itself; but if something is conceivable through itself, it is also in itself. Thus, *B* also implies *A*. The mutual implication makes *A* a necessary and sufficient condition of *B*, and vice versa.

Several hundred sentences in the *Ethics* are formed as some sort of equivalences: “Desire (*cupiditas*) is nothing else than the *conatus* itself to act” (IVP59Dem); “Desire considered absolutely is man’s essence itself . . .” (IVP61Dem); “. . . considered to possess the same sort of eternity or necessity . . .”; “The cognition of bad (*malum*) is the sorrow (*tristitia*) itself insofar as we are conscious of it” (IVP64Dem); “. . . God or Nature . . .” (IVP41Dem); “From the necessity, or (which is the same thing), from the laws only of the divine nature . . .” (IP17Dem).

Chapter 3 makes the transition into parts III and IV of the *Ethics*, introducing the predicates “understanding,” “freedom,” and “action” and linking them to the fundamental dual distinction.

It is seen, I hope, in chapters 4 and 5 how Spinoza’s positive attitude toward emotions and his belief in unlimited progress of freedom are linked to his basic metaphysical distinctions and propositions. I also hope to explain how he can speak of a genuine road toward freedom in spite of the seemingly prohibitive absoluteness of the fundamental dual distinction introduced in part I. There, man is unfree, fragmentary, impotent—he falls on the wrong side of a seemingly knife-sharp partition between in itself and in something else. In parts III, IV, and V, however, the partition is softened. Accordingly, I substitute for hard dichotomies a parallel set of graded predicates. This is done in chapter 4, which introduces the great turning point in my reconstruction. As will be seen, Spinoza himself suggested grading in the latter part of the *Ethics*. The softening is thus not arbitrary; it represents an implementation of some suggestions made by Spinoza himself.

In chapters 6 through 9, central notions such as “joy,” “good and bad,” “useful,” “virtue and reason,” and “self-satisfaction” are discussed using terms introduced in the preceding chapters. Whereas *substance*, *attribute*, and *mode* are eliminated, some basic scholastic terms, such as *in itself*, are retained in the reconstruction. This inevitably raises a question regarding the

extent to which the present reconstruction will be accessible to people with no special training in scholastic philosophy.

It is hoped that in what follows light will be shed on the term *in itself* through the suggestion of extensional equivalences. If some of these prove satisfactory, to be “in itself” can, in a preliminary way, be understood by concentrating on “that which can be conceived by itself” and its relatively easily understood counterpart, “that which can only be conceived adequately by also conceiving something else.” Or one may choose one of the other equivalences.

One may obtain access to the function of a group of extensionally equivalent terms by starting with those that are most readily understood. Say, for example, that term *A* is fairly well understood in its uses in contexts *a*, *b*, and *c*, whereas *B*, well understood in *d*, *e*, and *f*, is less understood in *a*, *b*, and *c*. By transferring *B* to contexts *a*, *b*, and *c*, one can obtain a better understanding of *B*. In this way the equivalences asserted in what follows can assist in an understanding not only of the conceptual links between the fundamental terms of part I and the conceptual framework of parts III and IV, but also—to a modest degree—of the terms themselves.

What I am trying to do, as indicated by the subtitle of the work before you, is to clarify the structure of a central part of Spinoza’s *Ethics*. If his system is presented as a vast circle, the central parts may be likened to the area of a smaller circle within the larger one. The different central parts of the *Ethics* are then parts within the smaller circle. How they should be conceived in their intimate relation to one another I do not pretend to know. The present study draws inspiration from the clearness and broadness of certain interconnections within the system. It does not pretend, however, to cover all central parts nor, of course, the system as a whole. Nevertheless, the system can be conceived adequately only as *a whole*. I shall assume that the reader has some very general conception of this whole, as I cannot furnish more detail within the confines of this study.

I

The Fundamental Dual Distinction: “In Itself” and “In Something Else”

Survey A

(“Add” preceding a survey entry marker denotes an addendum to the entry above it.)

- A₁ That which is, is either in itself or in something else.
- Add A₁ This is a rendering of the ontological IA₁. Later (in chapter 4), I shall take A₁ to mean “That which is, is either *totally* in itself or partly in itself and partly in something else.” The word *sunt* in *Omnia quae sunt* is open to various interpretations that I gloss over just now. Later, for instance, I shall be compelled to distinguish between “*x* exists” and “*x* is,” saying that that which is completely in itself does not exist, and that which exists is not completely in itself.
- A₂ That which is in itself is that which does not require something else in order to be.
- Add A₂ Ontological parallel to the mixed ontological-lambanological ID₃. In chapter 4, the following graded interpretations are adopted: “That which is totally in itself is that which does not at all require something else in order to be” and “That which is in itself in all relations is that which does not in any relation require something else in order to be.”
- A₃ That which is in something else is that which requires something else in order to be.
- Add A₃ From A₁ and A₂, using A₁₆. Ontological parallel to A₆. Interpretation to be introduced in chapter 4: “That which is partly in something else is that which requires something else in order

THE FUNDAMENTAL DUAL DISTINCTION

to be.” Similar interpretations are adopted in relation to A4 and A5. We say “in order to be” rather than “in order to exist,” taking “to be” as a wider property than “to exist” for the reasons stated in chapter 4.

- A4 That which is, is in itself if it is not in something else.
- Add A4 Ontological parallel to the lambanological IA2. Following Spinoza, we might reformulate A4 as “That which is must be in itself if it cannot be in something else.” Some logicians expect to clarify Spinoza’s thought by applying modal logic. However, I think the value of this approach is limited. Necessity is such a pervasive notion in the *Ethics* that it does not suggest fruitful contrasting properties within the system of theorems.
- A5 That which is, is in something else if it is not in itself.
- Add A5 Based on A4 and A1, that is, ultimately on IA1. It is doubtful that Spinoza tried to express anything special by giving IA2 a modal form. It seems that he might as well have given most or all other basic sentences that form. Thus, that which *is* in itself *must be* in itself, and *cannot be* in something else, it seems. IA1 might therefore have been formulated thus: “That which is either must be in itself or must be in something else.” Since the being of all things follows by necessity from God, IA1 might even be given the form: “That which *must be*, either *must be* in itself or *must be* in something else.” And A6 might be given the modal form: “That which must be, either must be conceived through itself or must be conceived through something else.” There seems to be no definite limit to this way of introducing modal terms. But the introduction of modal forms creates unnecessary logical complications. Therefore, in what follows, the modal versions are not listed independently of the nonmodal versions of theorems.
- A6 That which is, is conceived either through itself or through something else.
- Add A6 Lambanological parallel to IA1. In chapter 4, A6 is understood to mean “That which is, is conceived either totally through it-

self or partly through itself and partly through something else.”

It may be argued that there are many things that never happen to be conceived; for instance, many whirling snowflakes in the Antarctic. It may therefore be argued that that which is conceived, whether through itself or through something else, is only a minor part of that which is. Thus, A6 should read: “That which is *conceived*, is conceived either through itself or through something else.” If “*x* is conceived” is taken to be shorthand for “*x* is now at this moment actually conceived by at least one adult human being or by another kind of being capable of conceiving,” the reflection is valid. *Conceived*, however, should be viewed in a wide sense, closer to “conceived or conceivable.” Using this broad sense, we tentatively posit, “That which is, is conceived and that which is conceived, is.”

- A7 That which is conceived through itself is that which is such that its conception does not require any other conception in order to be formed.

- Add A7 Based on ID3, *Conception* is preferred to *concept* because of the static and conceptualistic associations of the latter term.

- A8 That which is conceived through something else is that which is such that its conception requires at least one other conception in order to be formed.

- Add A8 Formed from A6 and A7 using A1 (which is drawn from IA1).

- A9 That which is not conceived through something else is conceived through itself.

- Add A9 The lambanological parallel to IA2. The full importance of this axiom and the closeness of the relation between the lambanological and ontological aspects become apparent in IP8Sch2. Spinoza says that we can have true ideas about nonexistent things if and *only* if they require other conceptions through which they are conceived and these other conceptions refer to existing things. But we cannot have true ideas of a substance in

THE FUNDAMENTAL DUAL DISTINCTION

this way—to have those, we must be directly confronted with substance as it is. The truth of the idea can only be a reflection of this *confrontation* (cf. Edmund Husserl’s account of our awareness of the validity of the principle of contradiction). “If therefore somebody would say that he has a clear and distinct, that is, true idea of a substance, and nevertheless doubts whether it is false . . . that would amount to at the same time saying that he had a true idea, but nevertheless doubted whether it was false. . . .” The confrontation implies an elimination of the distinction between the subject and the object of cognition: substance is conceived through itself, that is, without our forming an idea that copies or mirrors the properties of substance. No comparison of idea with *ideatum* is necessary. Falsehood is excluded a priori.

This interpretation of the conception of “that which *is in* and *is conceived through* itself” is the only one, so far as I can understand, that explains satisfactorily the fundamental parallelism between epistemology and ontology in the *Ethics*.

- A10 That which is not conceived through itself is conceived through something else.
- Add A10 Based on A9 (IA2) using A6.
- A11 That which is in itself is that which is such that its conception does not require any other conception in order to be formed.
- Add A11 Derived from definition ID₃ when the latter part of it is considered to be related to the whole expression “that which is in itself and is conceived through itself.” Let us call it the holistic interpretation of the conjunction. This conjunction is found in many other places in the *Ethics*; see, for example, IP₂Dem and IP₁₅Dem.
- A12 That which is in something else is that which is such that its conception requires at least one conception of something else in order to be formed.
- Add A12 Derived from A1 and A11. See also IP₈Sch2, the sentence “*Per modificationes*. . . .” Spinoza refers to other things in which a

thing may be, or through which it may be conceived. From the example offered of causes and also other features of the context and, of course, from the sentence “*Per modificationes. . .*” itself, I conclude that if x is in y or is conceived through y , y need not be God or substance. Two “in something else” relations must be distinguished: the (universal) relation of things in God, and the chain relations parallel to the cause-effect relations of being in something else.

- A13 That which is in itself is that which is conceived through itself.
- Add A13 From A7 and A11.
- A14 That which is in something else is that which is conceived through something else.
- Add A14 Derived from A8 and A12. Suggested by the second half of ID5.
- A15 That which is conceived through itself is that which does not require anything else in order to be.
- Add A15 Derived from A7 and A18.
- A16 That which is, either requires or does not require something else in order to be.
- Add A16 Ontological parallel to the lambanological A17. The importance of this and the following quasi tautology derives from their generality: “for anything whatsoever that is, it holds that . . .” This assertion of generality implies the meaningfulness or relevance of a distinction in *all* realms of that which there is.
- A17 That which is conceived either requires or does not require the conception of something else in order to be formed.
- Add A17 Lambanological parallel to the ontological A16, suggested by A7 and A8, together with A6.
- A18 That which does require something else in order to be is that which requires at least one conception of something else in order to be formed.

THE FUNDAMENTAL DUAL DISTINCTION

Add A18 An ontological-lambanological equivalence. Derived from A3 and A12.

Survey A Using Symbols

The foregoing theorems and what follows from them are more easily surveyed if certain symbols, made up from one or several capital letters, are introduced to designate properties or express concepts.

Symbols:

Single isolated letters have the following approximate meanings:

E	being (in a vague, inclusive sense) [from the Latin word <i>esse</i>]
N	not- [from Latin <i>non</i>]
S	itself [from Latin <i>se</i>]
A	something else [from Latin <i>alius</i>]
R	require something in order to something [from Latin <i>indiget</i>]
P	possibility, ability, power [from Latin <i>posse</i>]
C	conceive, understand [from Latin <i>concipere</i> , <i>intelligere</i>]

The symbols below, formed by joining two single capital-letter symbols, have the following meanings:

ES as in $ES(x)$	x is in itself <i>x in se est</i>
EA as in $EA(x)$	x is in something else <i>x in alio est</i>
CS as in $CS(x)$	x is conceived through itself <i>x per se concipitur</i>

RE as in RE(x)	x requires something else in order to be
CA as in CA(x)	x is conceived through something else
RC as in RC(x)	x requires another concept in order to be conceived

Spinoza sometimes uses the expression “not to be in itself” as at least extensionally equivalent to “to be in something else.” Perhaps he sometimes even uses the expressions as synonyms. To play it safe, I do not introduce “to be in something else” as simply the negation of “to be in itself.” There might be a third category depending on the interpretation of “to be” (*esse*). Consequently, I make use of a new symbol, EA, instead of just using -ES. (Negation, “it is not the case that . . . ,” I symbolize by a closed-up minus sign.) Similarly, it is tempting to introduce “conceived through something else” by simply negating CS, that is, by -CS. I have used the separate symbol CA, however, for the same reason indicated above.

A note concerning “being in something else”: Things that are in something else are in God. This is stated explicitly in IP23Dem. Is this, however, the whole point about being in something else? If it were, one would usually expect Spinoza to write “being in God” instead of “being in something else”—hiding what this something always and invariably would have to be. It is my contention that what is referred to is not always God even when, of course, everything is always also in God. The completely general property of being in God does not exclude something also being in something other than God. The term *being* is used here in two different senses.

Thought and extension are different according to Spinoza. I will express thought as being something different and something other than extension. Both are in themselves and are conceived by themselves as attributes.

Now, motion is not in itself and conceived by itself according to Spinoza. Extension is conceived through itself and in itself, but not so motion; it is conceived through something else, and its conception involves extension. Motion, being conceived through something else, is in something else, if we use Spinoza’s conception of being in something else. Motion is in something else, namely, in extension. Motion is also in God, but, at least conceptually, extension is not the same as God.

THE FUNDAMENTAL DUAL DISTINCTION

Motion is not in the attribute thought. Although neither motion nor thought can be distinguished extensionally from God, both can be distinguished conceptually. This implies that the predicate “to be in something else” also applies to something different (at least conceptually) from God.

The conception of motion involves the conception of extension, but it also involves something more. If it did not, *only* motion could be involved in extension, since any other thing would then be conceptually indistinguishable from motion. If motion is to be differentiated from rest, and from other things conceptually dependent on motion, motion must be conceptually dependent on several conceptions, not just on extension. We are thus led to much more extensive and fruitful applications of the conception of “being in something else” than the merely repetitious “being in God.”

When two different things are completely understood and conceived through God, the formulation of the two conceptions cannot be identical. The second thing must be understood through something other than that through which the first thing is conceived. If when asking “How is this to be understood?” we always got the answer “Evidently, through God,” we would not be satisfied, nor would Spinoza.

The tremendous complexity of answers that Spinoza gives to questions of life and death, to questions of society and morals, is justified by a fundamental distinction between an understanding of something through God taken absolutely (*quatenus absolute consideratur*) and through God as affected some way or other (*quatenus aliquo modo affectus consideratur*).¹ God is also said to be modified by a verb corresponding to the noun *modus*. The difference between modes and God modified and affected in various ways is conceptual, not extensional. Thus, when something is in something else, namely, in God modified or affected in various ways, the something is in modes, and not only in God “considered absolutely.”

The understanding of the various human emotions gained in part III exemplifies conceptions through God because the emotions, or rather the human beings with emotions, are not completely in themselves but in something else—namely, God. Concretely, however, the understanding is described in terms of desire, appetite, acts, situations, personal developments, adequate and inadequate ideas, three kinds of human knowledge, and so on. That is, the modes or particular things are conceived through God as affected in various ways or, more explicitly, conceived through other modes or particular things.

The main thing to note in this work is that “in something else” (*in alio*) is used in a broad sense to do justice to both the relation between a particular thing and God taken absolutely and the relation between a particular thing and attributes, infinite modes, and (finite) particulars. In the latter cases, something may be conceived through a second thing, and therefore is in that thing, at the same time that this second thing is conceived through a third thing, and therefore be in that third thing. We thus have chains of relations corresponding through equivalences to the chains of cause and effect.

The following logical symbols are now introduced:

a	<i>aut</i> , the exclusive sense of “or”
∨	<i>vel</i> , the inclusive sense of “or”
&	conjunction “and”
⊃	material implication “if <i>A</i> then <i>B</i> ”
~	mutual implication “if <i>A</i> then <i>B</i> and if <i>B</i> then <i>A</i> ”
-	negation “not”
ekv	equivalence (“is extensionally equivalent to”)

Axiom 1 in part I of the *Ethics* (IA1), translated into English, reads, “All things that are, are in themselves or in something else.” Using our symbols, we write: $ES(x) \text{ a } EA(x)$. Because Spinoza routinely uses *vel* when *aut* would be closer to what he means, we must ask, Could there be an x such that it would be valid to say about this x : $ES(x) \text{ \& } EA(x)$? If $ES(x)$ is taken to mean fully or completely in itself, such an x does not exist. I wish to let $ES(x)$ in this part of the reconstruction stand for just this extreme case. Therefore, in what follows, the axiom receives the form $ES(x) \text{ a } EA(x)$ or, in my shorthand, $ES \text{ a } EA$. The eighteen theorems of survey A can now be reformulated using my abbreviated logical formula as:

Survey A

SA1	$ES \text{ a } EA$	IA1, ontological
SA2	$ES \text{ ekv } -RE$	ontological parallel to SA11

THE FUNDAMENTAL DUAL DISTINCTION

SA ₃	EA ekv RE	from SA _{3a} and SA ₂ ; ontological parallel to SA ₆
SA ₄	ES \supset -EA	ontological parallel IA ₂
SA ₅	EA \supset -ES	based on SA ₄ and SA ₁
SA ₆	CS a CA	lambanological parallel to IA ₁
SA ₇	CS ekv -RE	based on ID ₃
SA ₈	CA ekv RE	from SA ₆ and SA ₇
SA ₉	-CA \supset CS	lambanological parallel IA ₂
SA ₁₀	-CS \supset CA	based on SA ₉ using SA ₆
SA ₁₁	ES ekv -RE	from ID ₃ , holistically interpreted (cf. A ₁₁)
SA ₁₂	EA ekv RE	from SA ₁ and SA ₁₁
SA ₁₃	ES ekv CS	from SA ₇ and SA ₁₁
SA ₁₄	EA ekv CA	from SA ₈ and SA ₁₂
SA ₁₅	CS ekv -RE	from SA ₇ and SA ₁₈
SA ₁₆	RE a -RE	their logical form reduces A ₁₆ and A ₁₇ to tautologies
SA ₁₇	RC a -RC	lambanological parallel to SA ₁₆
SA ₁₈	RE ekv RC	from SA ₃ and SA ₁₂

Note on the application of symbolic logic: On reading the above symbolic versions, one should have in mind how the symbols \vee , ekv, &, and so on are introduced in a good elementary textbook that avoids unnecessary philosophical commitments and, as a corollary, has only heuristic pretensions as to what is gained by the use of symbols. The symbols used here are not meant to be anything more than convenient tools.

When we write ES ekv -RE, we do not pretend to symbolize (1) what Spinoza means by “in itself” or (2) what Spinoza means by “require something else in order to be”; we are only trying to symbolize the relation be-

tween (1) and (2). There is no way of measuring the semantical distance between the meaning intended by Spinoza and that of a symbolic construction. The distance is one of many dimensions, none of which has any generally recognized measurable unit. Here only some elementary points will be mentioned:

1. In IA1, which says “That which is, is either in itself or in something else” (*Omnia, quae sunt, vel in se vel in alio sunt*), the expressions *omnia* and *sunt* permit various, significantly different interpretations (pending conclusive results of Spinoza research). In connection with universal and existential quantification, I have reasons for avoiding (until chapter 4) these terms, which are among the most slippery in Spinoza’s terminology. We have avoided $\gamma_3(x)$: $E_{sp}(x) \supset ES(x) \vee EA(x)$; “For all x it holds, as an assertion expressing cognition of the third kind, that if x is [in the sense of Spinoza’s *Ethics* IA1], then x is in itself or is in something else.” This would lead to a premature multiplication of concepts.

The false view that there is a systematic difference between “*vel . . . vel*” and “*aut . . . aut*” in Latin, such that “*vel . . . vel*” corresponds to “ \vee ” and “*aut . . . aut*” to “ \wedge ,” made it natural to symbolize the axioms by $ES \vee EA$ rather than by $ES \wedge EA$. But even if only a small bit of context is taken into account, evidence accumulates that “*a*” (*aut*) is nearer than “ \vee ” (*vel*) to the intended meaning (within the rather special dimension of differences of meaning, which is relevant to the distinction between exclusive and inclusive “or”).

2. In rendering IA1 by $ES \wedge EA$ rather than by $(x): ES(x) \vee EA(x)$, we are deliberately simplifying matters by turning our attention away from the question of how wide the range of values of the predicates “in itself” (ES) and “in something else” (EA) should be, of how wide the class of existents is in Spinoza’s terminology, and of what class of *objects*, in a very wide sense of the word, is such that it suits the intended meaning of the general assertion made by Spinoza. We turn our attention away from questions of range, but the same questions of course relate to the formulas, even if we avoid symbols of quantification. Which are the ranges of the predicates? The question is left unanswered at this point.

THE FUNDAMENTAL DUAL DISTINCTION

There is little reason to expect that, for example, of the twenty most frequently used predicates in Spinoza's theorems, all have the same range of intended application or range of meaningfulness. I assume in what follows that IA1 is intended to apply to a definite, very wide range, and that this holds for all others symbolized in this work (for example, "free"), and that this range is exactly the same for all. This, of course, introduces a major simplification, and in Spinoza studies simplifications should always be welcomed as long as they are explicitly formulated and not too ahistorical.

In light of the undetermined ranges of variables, a tautology such as $RE\ a - RE$ (see SA16) is of interest because it says all x 's that make $ES(x)$ and $EA(x)$ meaningful also make $RE(x)$ meaningful, and vice versa.

3. If Spinoza's text affords evidence that three complex sentences A , B , and C form fairly adequate symbolizations of three theorems of the *Ethics*, each considered in isolation from the context, or at least in isolation from the total context of Spinoza's works, logical calculi permit us to derive a number of consequences in an easily testable way. If, now, D is a consequence and D is found to form a fairly adequate symbolization of a theorem, or of a not entirely trivial sentence that intuitively, or according to a rather obvious nonformal chain of reasoning, may be derived from theorems, this discovery is of sufficient interest to be noted. If a logician were to say that this sentence is logically derivable from A , B , and C (which are in harmony with Spinoza's text), and you do not need to note that D stands in a satisfactory relation to the text of Spinoza, the logician would be overlooking the fact that all symbolization is purely hypothetical as regards adequacy, however well tested in a broader context. Any confirmation of our hypotheses should therefore be noted. That D is adequate confirms the symbolization of A , B , and C .

It must not be taken for granted that the often rather strange conclusions that formal logic permits to be drawn from a set of premises are fit to be included in our set of symbolizations of sentences that harmonize with Spinoza's text.

This long note on the use of symbolic logic might be shortened considerably if there were not a tendency to overestimate the philosophical consequence of its use. If a housewife writes ES for Ellen's

syrup and EA for Ellen's apples and uses + and = in her economic calculations, we do not scold her for not having at the same time decided exactly what to express by EA, ES, +, and = in terms of, let's say, chemistry and number theory. Using symbols when surveying the complicated structure of Spinoza's terms and propositions does not make it necessary at the same time to take up all kinds of problems connected with the interpretation of the logical symbols and the predicates symbolized by letters. Our use of symbolic logic is heuristic, not an attempt to philosophize beyond the scope of the nonsymbolic versions of our theorems.

On the other hand, we do not intend to minimize the importance of the problems created by our simplification. We will try to pick some of them up along the road. One of the most difficult tasks we face when forming an exposition of a part of Spinoza's philosophy is just to avoid trying to say all things at once.

II

Existence and Freedom

Spinoza makes extensive use of the distinction between inconceivable things in the sense of things that we cannot conceive as real, existing things, and things that conceivably exist but in fact may or may not exist. About the latter, Spinoza says that they can be conceived, first, both to be and not to be and, second, to exist and not to exist. In addition, there are things (in the extremely broad sense of “thing”) that cannot be conceived not to be. Things that are completely conceived through themselves cannot be conceived *not* to be. The way, and the only way, to conceive them is just to be confronted with them in the act of conception. They cannot be introduced into a discussion in the following way: “I shall now describe to you the essential properties of something, x , and let us then discuss whether it exists or not” (cf. IP8Sch2). If this kind of introduction were possible, this x would be conceivable by means of something else, namely, the description of a set of properties of x .

Some would say that a red hue is either conceived through itself or not conceived at all. Introducing a red hue through the concept of wavelength or use of a color atlas does not help if one does not also have a perfectly direct access to hues. Spinoza would perhaps not agree to this, but the *kind* of argument concerning red hue is analogous to that on substance. Either you grasp it directly, and then you of course cannot avoid attributing existence to it, or you do not grasp it. In that case you do not know what Spinoza is referring to. Either you accept that substance exists, or you do not know what to look for.

There is, as already mentioned, a minor terminological problem confronting us at the very outset: is Spinoza in such contexts talking about being in some broad sense or being in a narrow sense of existing (being at hand, being so that it can be found) or of being in other senses? It seems that he is considering “being” (*esse*) in a broad sense. It is confusing that he

EXISTENCE AND FREEDOM

sometimes uses the term *existere* rather than the term *esse*, which better lends itself to broad senses.

We shall, in spite of the too narrow concepts usually expressed by the term *to exist*, nevertheless regularly translate *existere* to *exist*. This means that in our reconstructions, *exist* sometimes expresses what we have already announced shall be expressed by *being* and by *is*. In our special terminology, what is completely conceived through itself does not exist, but *is*. But it is too complicated to consistently carry through this terminology in our translations of Spinoza.

Spinoza often uses *existere* in a way that implies actual existence, “to be there,” *da seiend* in German. He then contrasts this with being involved (*involvit*). See, for example, his discussion of Euclid’s section 35 in book 3, IIP8Sch:

In a circle infinitely many equal rectangles are contained, and its idea *involves* all these rectangles. But they do not exist — “none of them may be said to exist.” Nor do we have any idea of them when we have an idea of the circle. But all the rectangles are nevertheless *involved* in the idea of the circle [my italics].

Survey B

- B₁ Something can either be conceived as nonexistent or cannot be conceived as nonexistent.
- Add B₁ This pretty vacant sentence introduces a new predicate “cannot be conceived as nonexistent.” It behaves as do the already introduced predicates “in itself,” “conceive through itself,” and so on, giving rise to a growing set of strict dichotomies parallel to the fundamental dual distinction. B₁ is only a postulation of the universal applicability of such a dichotomy.
- B₁ might be more carefully worded as follows: something can either both be conceived to be and be conceived not to be, or it cannot be conceived not to be. This version makes it clear that the possibility of something that *only* can be conceived not to be is left out.
- B₂ If something cannot be conceived as nonexistent, existence belongs to that without which that something cannot be conceived, and vice versa.

- Add B2 This theorem might be derived from B1 and “That which cannot be conceived as nonexistent can be and can only be conceived as existent” and “That which can only be conceived as existent exists.”

The expression “cannot be conceived except as existent” (*non potest concipi nisi existens*) occurs at the very beginning of the *Ethics*, defining “cause in itself.” In ID1 Spinoza speaks about something the *nature* of which cannot be conceived except as existent. If we take *nature* here not to be different from *essence* in IID2, it seems that if the nature of something cannot be conceived except as existent, then that something itself cannot be conceived except as existent. Therefore, for simplicity’s sake, *nature* or *essence* is not used in B1 and the propositions that follow (We do *not* say “The nature [essence] of that which is conceivable can either . . .”). The near synonymy of *nature* and *essence* in the kind of context studied here manifests itself in IP7Dem, where “*x* is a cause of itself” is equated with both “*x*’s essence necessarily involves existence” and “it belongs to the nature of *x* to exist.”

Preferring *is* to *exists*, we might phrase B2 as follows: if something cannot be conceived not to be, being belongs to that without which that something cannot be conceived, and vice versa.

- B3 If something can be conceived as nonexistent, existence does not belong to that without which that something cannot be conceived, and vice versa.

- Add B3 The expression “that which can be conceived as nonexistent” occurs in IA7. A little later it occurs in the treatment of the existence of God. Proposition B3 is derived in part from the definition of *essence* (IID2): “To the essence of a thing belongs, I say, that which, if given, the thing is necessarily posed [*ponitur*], and which, if not given [*sublato*], the thing is necessarily removed [*tollitur*].”

In the formulation of B3, “If something can be conceived as nonexistent, existence does not belong to *that without which . . .*,” the italicized part is a substitute for the phrase

EXISTENCE AND FREEDOM

its essence and is identical with the last part of the definition of essence, IID2.

- B₄ If something can be conceived as nonexistent, it is conceived through something else, and vice versa.
- Add B₄ The “something else” is God as modified or affected, somehow.
- B₅ If something cannot be conceived as nonexistent, it is conceived through itself, and vice versa.
- Add B₅–
B₂₁ This and the following propositions, except B₁₀, are derived from the foregoing propositions and A₁–A₁₈ in elementary ways. Those interested are referred to the right-hand column in the symbolic version of Survey B, p. 28.
- B₆ If something can be conceived as nonexistent, it is conceived by something else, and vice versa.
- B₇ If something cannot be conceived as nonexistent, it is in itself, and vice versa.
- B₈ If something can be conceived as nonexistent, it requires the conception of something else in order to be conceived, and vice versa.
- B₉ If something can be conceived as nonexistent, it requires something else in order to be, and vice versa.
- B₁₀ If something is free, existence belongs to that without which it cannot be conceived, and vice versa.
- Add B₁₀ The term *free* (*liber*) occurs for the first time in ID₇. Something free is said to exist alone from (by force for) the necessity of its nature. Another characteristic is added (in the form of a conjunction). Each member may be taken as self-sufficient, and we choose the first. Eliminating *essence* for *nature*, we apply the definition of essence (IID2). This gives us B₁₀.
- B₁₁ If something is unfree, existence does not belong to that without which it cannot be conceived.

- Add B11 In part I, Spinoza uses *free* for “completely, absolutely free.” *Un-free* is then synonymous with “not completely, absolutely free.”
- B12 If something cannot be conceived as nonexistent, it is free, and vice versa.
- B13 That which is unfree is such that existence does not belong to that without which it cannot be conceived.
- B14 The free is that which is in itself.
- B15 The unfree is that which is in something else.
- B16 The free is that which is conceived through itself.
- B17 The unfree is that which is conceived through something else.
- B18 The free is that which does not require something else in order to exist.
- B19 That which is free is that which does not require the conception of something else in order to be conceived.
- Add B1–
B19 The availability of these theorems taken in isolation is doubtful and precarious to the modern mind. Intensive studies of scholastic and Aristotelian ontology are necessary, and even then, conclusions tend to differ dismally. The aim of our structural analysis at this point may be formulated quite simply as follows: to lessen the burden of understanding by pointing to properties that are easier to grasp and that are extensionally equivalent with the more difficult ones. The system of Spinoza is largely available on the extensional level. Complete understanding of connotations is perhaps beyond our capacities but also largely unnecessary for the application of his philosophy to the problems of human life.

Most of these theorems are obvious derivations from a small set. Why then extend the exposition to such a length? Because careful and extensive derivation from propositions firmly based on the text of the *Ethics* reveals hidden structures and supports conclusions of importance to any coherent, understandable interpretation.

Survey B Using Symbols

New Symbols:

PCNE(x)	it is possible to conceive x as nonexistent
ENPC(x)	existence of x belongs to that without which x cannot be conceived
L(x)	x is free (<i>liber</i>)

Again, for the sake of brevity, we employ the abbreviated logical formulas.

III

Causation, Cognition, and Action

The Hypothesis of Cognitive-Causal Parallelism

In what follows I make use of a general *hypothesis of parallelism*:

If and only if y can be conceived through x , is x the cause of y ; and if and only if x is the cause of y , can y be conceived through x .

The parallelism between causing and the possibility of conceiving is based on the structural parallelism of theorems of causing and conceiving in Spinoza's text. In interpreting the formulation of the hypothesis in various directions, we have had seventeenth-century uses of the Latin *causa* in mind, not every modern use of *cause*.

It should also be borne in mind that the cognition in Spinoza is not the Platonic mirroring but a dynamic process not to be separated from action. The parallelism is therefore better characterized as lambanological-causal. We grasp and, when grasping, act as causes.

For certain classes of x and y , the hypothesis of parallelism is directly and strongly confirmed by references to places in the text of the *Ethics*; for other classes, there is confirmatory evidence of a more or less indirect character. For still others, there is neither direct confirmatory nor direct disconfirmatory evidence. This is the largest class, comprising relations between particular things different from persons. There is, taken all together, more support for the hypothesis than for its negation: "there are x 's and y 's such that although y can be conceived through x , x is *not* the cause of y ; and there are y 's and x 's such that although x is the cause of y , y cannot be conceived through x ."¹

It is not possible to subsume all occurrences of "adequate" (*adequatus*) conception or cognition and causation under a single concept. The particu-

lar concept that is preferred in what follows is directly supported by many passages, for instance by IIP29Sch:

I say expressly that the mind has no adequate but only confused cognition (*cognitio*) of itself, of its body, and of external bodies, when it perceives a thing in the common order of nature, that is, whenever it is determined externally, that is, by fortuitous circumstances, to turn its attention to this or that, and not when it is determined internally, that is, by turning its attention to many things at once, to understand their agreements, differences, and oppositions one to another.

From the above, I infer the following sufficient condition of adequate cognition and conception: A thing (*res*) is an object of adequate cognition and conception when it is conceived in relation to many things (*res*), and when agreements, differences, and oppositions have been noted. Sometimes, but not always, Spinoza uses *in part* (*ex parte*) as a synonym for *inadequate*. This is clear in IIP11Cor, in which he uses the expression “in part or inadequate.” This criterion is well suited as a description of cognition of the second kind (in the terminology of IIP49Sch2).

An example of adequate cognition is an act. It is internally determined and caused, whereas inadequate cognitions are externally determined and caused. That is, the cognizer is active in the former kind of situations and passive in the latter.

The emphasis on “many things” suggests the organic conception of nature. Particular things have internal relations to others in such a way that isolation and delimitation are more or less arbitrary. That a thing is only cognized “in part” should be interpreted as “only in parts of its relevant connections with others.” Particular things are only more or less arbitrarily (fortuitously) isolated parts of more comprehensive (also more or less fortuitously isolated) units, which together form total nature.

One special concept, ‘inadequacy of conception’, is based on this “partiality” relation, making it natural to say that we perceive a thing partially or, in other words, inadequately, *ex parte sive inadequate* (IIP11Cor). Inadequacy may certainly be interpreted in other directions, but the concept of partial perception will carry us quite far, and it has the merits of clarity and simplicity on its side.

If we take things to be thoroughly immersed in fields or structures of relations, we must recognize that any attempt to isolate or abstract from

these relations will result in some inadequacy in perceiving and conceiving things.

In what follows, “inadequate” is taken in an approximate sense of “taking things in isolation, one by one, as in the common order of nature.”² A somewhat more nuanced distinction will be introduced when the fundamental predicate is graded. A rather arbitrary isolation of a thing from internally related contexts may yield cognition that is good enough for certain purposes in limited practical situations. The central metaphysical importance of the awareness of arbitrariness does not exclude the central practical importance of isolation. This is one reason for stressing the adjective *partial* rather than *inadequate*. A partial conception of something may in a sense be just what is needed in a practical situation. I say “in a sense” because the awareness of the partiality and arbitrariness must somehow be required in order for so-called practical, everyday problems to be solved within the framework of the good life or the complexity of human social organization.

In what follows, “inadequate cause” is taken to be a partial cause. There is nothing wrong with inadequate causes—they are just not the total cause of anything! The problems confronting the interpretation of *inadequate* as applied to causes are considerably less heterogeneous than those applied to cognition. In the latter context, one must take up questions concerning inadequate *ideas*—a formidable nest of unsolved problems of interpretation and consistency.

Using the general hypothesis of cognitive-causal parallelism stated at the opening of this chapter, I shall now turn to a systematic presentation of some theorems.

Survey of Theorems

Causation, Understanding, and Existence

C₁ If something is the adequate cause of something, the latter can be adequately conceived through the former.

Add C₁ IA₄, IIID₁, IIID₂, IIIP₁, and IIIP₃.

As an example of positive evidence of C₁, let us take IP₃Dem. Here, Spinoza wishes to demonstrate that if a thing *x* has nothing in common with a thing *y*, *x* cannot cause *y*. He uses IA₅, from which he infers that if

x has nothing in common with y , y cannot be intelligently understood through x . The lack of understandability he then takes as proof of lack of causality. He also uses IA4, saying that the conception of the effect depends on and involves the conception of the cause. Thus, we may rely on a criterion “ x is not the cause of y ,” namely, “ y cannot be understood through x ,” and vice versa.

In order to tackle one difficulty at a time, I frequently use the term *adequately conceived* to cover the terms *understood* and *adequately understood* (Latin terms: *concipere*, *intelligere*). We take “ x is conceived” to be a necessary but not a sufficient condition of “ x is understood,” elevating “understanding” to a higher level. The term *conceived*, already used in chapters 1 and 2, we shall interpret in chapter 3 to mean “adequately conceived.” Thus, when making use of, for example, A10, we take it to be synonymous with “What cannot be *adequately* conceived through (itself plus) something else. . . .”

In IIID1, both *percipi* and *intelligi* are used. It is not difficult to find reasons for *percipi* meaning something different from *concipi* here, but the system of Spinoza seems to require that *concipi* might have been used in IIID1.³

I have therefore retained the old terminology from chapter 2, using the term *conceive*.

- C2 If something can be adequately conceived through something, the latter is an adequate cause of the former.

- Add C2 This is only the converse of C1. In its generality, it cannot be based on any explicit proposition of the *Ethics*. However, C2 does not contradict any such proposition. Moreover, the negation of C2 would lead to inconsistencies or unanswerable problems.⁴ The absence of a possibility of understanding is taken to be a sufficient condition for the absence of a causal relation.

- C3 That which is an adequate cause of something is something through which that thing can be adequately conceived, and vice versa.

- Add C3 From C1 and C2. The phrase *and vice versa* is added to eliminate an important ambiguity. The ambiguity often makes itself felt when Spinoza says that something, A , *is* something else, namely, B . Is B in such cases also A ?

The modal expression “can be conceived” is used, but later we will use the simpler “is conceived.” We write “an adequate cause” rather than “the adequate cause,” because we will not exclude the possibility of there being many adequate causes. Some causes may be reduced to others. For instance, *A* and *B* might both be adequate causes of *C*, but only *A* might also be an adequate cause of *B*. Then we may say that cause *B* of *C* can be reduced to cause *A*, or *A* to *B*. Here only one of the two is sufficient to be taken as an adequate cause. In other cases, no such reduction of two to one might be possible.

In C1–C3, “cause” is meant to be taken in a wide sense to cover many important subclasses of causes.⁵ This also makes it prudent not to postulate that if *A* is an adequate cause of *B*, then it is the only one (even at the level of connotations). God or substance is always an adequate cause of each and every thing, but as we shall see, a person may also be an adequate cause of something. This suggests that when cause is taken in a sufficiently wide sense, there may be two adequate causes of something. It is unlikely that we can fully understand what Spinoza personally meant by *causa*.

- C4 If something is an inadequate cause of something else, the latter can only be inadequately conceived through the former.

- Add C4 Suggested by IIID1. Instead of *inadequate*, we might say *partial*, *ex parte* (IIP11Cor). In the long run, the part/whole distinction seems to offer the most coherent versions of Spinoza’s system. It is also more understandable or accessible for contemporary readers.

- C5 If something can be inadequately or partially conceived through something else, the latter is an inadequate or partial cause of the former.

- Add C5 The term *partial cause* occurs in the last phrase of IIID2. By analogy, we introduce “partially” and “inadequately” conceived.

- C6 That which is an inadequate cause of something is something through which that something can be inadequately conceived, and vice versa.

CAUSATION, COGNITION, AND ACTION

- Add C6 From C4 and C5.
- C7 If something is the adequate cause of itself, it is (adequately) understood through itself.
- Add C7 As a particular case, where the two somethings x and y of previous propositions concerning “ x causes y ” are the same, we arrive at the notion of *causa sui*. As a corollary we construct a notion “ x conceived by x ” (*conceptus sui*—if we permit ourselves to form our own Latin). By means of ID₁ and IID₁, we make a connection between “adequate causation” and “conceived through itself.”
- C8 If something is understood through itself, it is the adequate cause of itself.
- Add C8 Modal version: if something is capable of being understood through itself, it is the adequate cause of itself.
- C9 An adequate cause of itself is something that is (adequately) understood through itself, and vice versa. (So much for parallelism between causation and conceiving!)
- C10 If something is adequately caused by itself, existence belongs to that without which it cannot be conceived, and vice versa.
- Add C10 According to ID₁, “ x adequately causes x ” is equivalent to “the nature of x cannot be conceived except as existent.” Using the definition of essence (IID₂), we reformulate this as “existence belongs to that without which x cannot be adequately conceived.” This property has already been introduced in chapter 2. Thus, we are entitled to base C10 on ID₁ and IID₂.

By means of these propositions, causation and understanding are connected with notions previously introduced. It is therefore easy to derive many propositions of interest by cross-references. As it is more convenient to survey the relation when certain symbols are introduced, a sample of such propositions will only be formulated in their symbolic form.

Activeness

Activeness is so central to Spinoza's world outlook that it should be formally introduced in our reconstruction as early as possible.

A free thing is said, in ID7, to be one that is determined to act (*agere*) or, rather, to be active solely through or from or by itself (*a se sola ad agendum determinatur*). The supplement *be active* is crucial because, according to Spinoza, emotions are forms of *agere*, although scarcely actions in any standard use of *to act*.

Surveying the applications of the term *to be active* (*agere*), we may safely link it to activeness in a wide, positive ("metaphysical") sense, with *being passive* (*pati*), being acted on, sometimes as its opposite, sometimes as a particular way of *agere*, namely, the *more or less* passive way (IIID2, IIIP1, IVP2).

We should not expect these terms to behave exactly as *to be active* and *to be passive* do in current everyday usage. *Agere* is used as part of the technical vocabulary of the system, and it applies to all living things, perhaps all particular things whatsoever. I use it in relation to all living beings in my reconstruction.

The numbering of theorems in the following shows lacunae that are eliminated in the symbolic version, which also introduces some less interesting but necessary propositions. We shall now link "to be active" with "to cause," taking IIID2 as a starting point.

- C30 If x causes y adequately, x is completely (wholly) active in relation to y .
- C32 If x is completely (wholly) active in relation to y , x causes y adequately.
- C34 If something is completely active, it is always an adequate cause, and vice versa.
- C36 If y is understood through x , then x is completely active in relation to y , and vice versa.
- Add C36 From the extensional equivalence of causation and understanding we thus derive an extensional equivalence between "being completely active" and "understanding" (in relation to something).

The above theorems map out the fundamental structural relations of causation, activeness, and understanding.

Even though it is not part of our reconstruction, it is difficult to avoid giving at least a tentative answer to a burning question of content: what would be a typical attitude or behavior such that Spinoza would say it manifests those structures?

Suppose a person makes a hat from leaves and places it on his head. The making of the hat and the covering of the head might be understood (or completely conceived) through him, that is, knowing his personal inclinations and purposes. In this case, he adequately causes the hat and covering to exist, and he is completely active in relation to the hatmaking and covering of his head. This is not the same, however, as to assert sweepingly that a hat in all its total relations to other things is completely conceivable through the hatmaker. We are talking only about a particular event. The hat is an extremely complex phenomenon—as all natural objects are unfathomable and give unlimited opportunities for research. What was said above has to do with particular, temporal acts of the hatmaker and the effects of these acts.

Similar remarks are relevant to causing as it relates to conceiving. Another example: The engineer, having designed and erected an enormous tower as part of the equipment for transporting electricity, is highly active in relation to the tower and a wider field of relations involving the tower. However, the division of labor atomizes and makes highly abstract and incomplete the technical creations. Here, of course, one may dive into the philosophy of labor as developed by Hegel, Marx, and others and connect Spinoza with the deep ecology movement (Naess 1973 [in SWAN XI]).

The complete activeness of a person's relation to nonliving things is relatively unproblematic. On the other hand, we can scarcely say that a person *A* can be completely active in all relations to another, *B*. *A* cannot possibly be the total cause of *B* as long as *B* retains his personhood, and *B* could not possibly be fully conceived through *A*.

All particular things have an essence; they are not “completely in something else.” Can *A*, however, totally cause the essence of *B* if *B* is not a person? This seems to be the case. People do make new things (but not natural objects!). After something is made, it has an existing essence and it may cause still more things. Counter to this it may be argued that a particular thing *in extenso* is only partially made by man. He does not *create* particu-

lar things. “A causes B totally” may tentatively be limited to aspects or properties or partial relations of things, if A is not God.

Sub specie aeternitatis, only substance or God is the adequate cause, but this reflection does not concern us here. We are, in taking God into account, concerned by God “insofar” or “as (*quatenus*) affected by something.” This is one of the reasons that we do not introduce the term *God (Deus)*.

So much for adequate or total relations. Considerations of symmetry speak strongly in favor of linking partial activeness with partial causing and partial conceiving.

C39 If x is an inadequate or partial cause of y , x is partially active in relation to y .

C40 If x is only partially active in relation to y , x is an inadequate or partial cause of y .

Add C40 Spinoza’s system does not contain any notion of complete passivity, that is, passivity in all relations. From theorems C39 and C40 we may infer that passivity for Spinoza is a low grade of activeness, not the absence of it. In some relations, particular things may be completely active and in others, completely passive.

Human Beings as Part of Something Else

Spinoza stresses the fundamental characteristic of a person as one particular among other particulars. He also stresses the infinitesimal smallness of an individual’s power in relation to that of the rest of the field of particulars—nature as a whole—and he dwells on the slavery of the immature person under the passive emotions. The following theorems give expression to the location of human beings among those things that are in something else, that are conceived through something else, and so on.

C43 If x is a person, x is in something else.

C45 If x is a person, x is conceived through something else.

C47 If x is a person, x can be conceived as nonexistent.

A person is part of something, and personal identity is relational. Human beings are not part of something in the same way that quartz crystals are part of sand, but rather in the way that oxygen is part of water. Human beings exist *in* the personal relations, as a changing center of interactions in a field of relations. Human beings are not an ultimate constituent of anything. Neither human beings nor the things they relate to exist, as such, apart from these relations. The relata exist only in the relation. This is, briefly, the *relationism* of Spinoza.

Some of the personal relations are such that through them human beings can be said to cause adequately, to conceive adequately, and to act in a given situation without any ingredient of passivity.

On the basis of such considerations, an account of personal identity may be tentatively constructed. After all, it is scarcely an absolute, timeless identity we seek, but something slightly less ambitious. Ruth Saw (1969) seems to find difficulty in giving an account of personal identity in the sphere of extension, but the flame of a candle burning in quiet air provides a good model of “identity in interaction.” The particles that move rapidly upward do not define the flame in spite of its being made up from these particles (according to Spinoza and others). A person can be conceived to have the flame aspect extensionally and the unified-soul aspect nonextensionally. This brings us to the brighter side of Spinoza’s teaching: human beings do not always in all relations cause or conceive something only partially.

C52 Every human being conceives something adequately.

According to IIP47, human beings have an adequate conception of God’s essence. From previous propositions used in proving IIP47, it can be shown that Spinoza also acknowledges other adequate conceptions that are not peculiar to privileged persons but belong to all of us. Thus, there are “common” adequate ideas (IIP38, IIP38Cor). Further, the proof of IIIP1 opens with “Of the ideas of the human mind, some are adequate, others fragmentary and confused.”

C54 Every human being causes something adequately.

When a human being conceives something adequately, he ipso facto causes something adequately according to our hypothesis of parallelism

(C2). The theorem is further supported by the doctrine of man's *active* emotions. We are their adequate causes (cf. IID3, italicized addendum).

Thus, even though human beings start low on their road to freedom, as more or less slaves of passive emotions, they have the necessary causal and cognitive endowment to crawl upward. There are no emotions (according to VP4Cor) from which we cannot form an adequate idea. They all can develop into active emotions.

Instead of "human being" in C52 and C54 one might write "adult human being," taking account of Spinoza's view of children. In his discussion of the stone that believes it is falling from free choice (*Letter* 58), Spinoza seems to take the level of freedom of small children to be somewhere between that of a stone and that of adults.

From the assertion that a human being is sometimes an adequate cause of something, and thus that something can be adequately understood through him, we may infer that in certain relations human beings are *in se*, not *in alio*. In these limited relations or, better, interactions, man has a god-like ontological status that Spinoza does not stress in spite of its existence as a requirement of his system. The interdependence of God or substance and the modes may also be argued forcefully in this connection: When I am an adequate cause of an action, it can be fully understood through me. I am "*in se*," "independent of anything else," and thus, in this relation, like God. The act cannot be, nor be understood, without me. It is "*in me*."

Without the act, without the medium, I cannot be, nor be understood, even in this relation. Thus, I am *in one important sense* always dependent on something else. Unlike God, that is, the totality? No. The same holds for God or substance. Without the mode, nothing is left of God or substance. It is an unavoidable consequence of the principle of immanence.⁶

Survey C Using Symbols

New Characters in Symbols:

H	person, <i>homo</i> , <i>nos</i>
Ad	adequate
In	inadequate

CAUSATION, COGNITION, AND ACTION

New Symbols:

$D(xy)$	x is a cause of y , adequate or inadequate, partly or totally
$InD(xy)$	x is an inadequate cause of y , x is partly a cause of y
$AdD(xy)$	x is a cause of y , and not inadequately; x is an adequate cause of y , x is a total cause of y
$C(xy)$	through x , y is conceived in part or in toto, adequately or inadequately
$InC(xy)$	through x , y is conceived in part or inadequately
$AdC(xy)$	through x , y is conceived, and not inadequately, but adequately; through x , y is adequately conceived
$G(xy)$	x is active in relation to y , adequately or inadequately, partly or totally
$InG(xy)$	x is passive in relation to y ; x is inadequately (only partly) active in relation to y
$AdG(xy)$	x is adequately or totally active in relation to y
$H(x)$	x is a person
$E(xy)$	x is in y

To avoid the unrewarding complexity of modal logic, we do not picture the “can” in “can be conceived” in our symbols, writing $C(xy)$ indiscriminately for “through x , y is in fact conceived” and “through x , y can be conceived.” If “in fact” is taken in a purely realistic way, no causation between x and y occurs in nature except when there is somebody who actually conceives y through x . This is a drastic kind of “idealism” foreign to Spinoza.

For the sake of simplicity, I use only the two variables x and y . A third variable would help in making the symbolization more adequate: $AdD(xyz)$ — “ x is an adequate or total cause of y in situation (context, relation) z .” When a person does something freely, he causes something adequately, but it happens within a context, not in complete generality. One might, of course, define the two-valued D in such a way that the context is

included as a conceptual characteristic, making y limited to context; but that is terminologically awkward. Introducing this third variable will be convenient in certain later sections.

Survey C

The first nine theorems concern the relations between causality and understanding.

SC ₁	$\text{AdD}(xy) \supset \text{AdC}(xy)$	Based on the first part of IIID ₁ and on IP ₃ Dem. “If something causes something else adequately, the latter is conceived, and not inadequately, through the first.” “If x is an adequate cause of y , y is adequately conceived through x .”
SC ₂	$\text{AdC}(xy) \supset \text{AdD}(xy)$	Based on IIID ₁ , first part. “If something is conceived adequately through something else, the latter causes the former adequately.” “If y is adequately conceived through x , x is an adequate cause of y .”
SC ₃	$\text{AdD}(xy) \sim \text{AdC}(xy)$	From SC ₁ and SC ₂ . Based on IIID ₁ , first part. “There is mutual implication between adequate causation and adequate conception.”
SC ₄	$\text{InD}(xy) \supset \text{InC}(xy)$	Based on the second part of IIID ₁ . “If x is a partial cause of y , y is conceived in part through x .”
SC ₅	$\text{InC}(xy) \supset \text{InD}(xy)$	Based on the second part of IIID ₁ . “If y is in part conceived through x , x is a partial cause of y .”

CAUSATION, COGNITION, AND ACTION

SC6	$\text{InD}(xy) \sim \text{InC}(xy)$	From SC4 and SC5. Based on IID ₁ , second part. “There is mutual implication between causation (<i>ex parte seu inadequate</i>), and conception (<i>ex parte seu inadequate</i>).”
SC7	$\text{AdD}(xx) \supset \text{AdC}(xx)$	From SC1. Cf. ID ₁ and IIID ₁ . “If something causes itself adequately, this something is conceived adequately through itself.”
SC8	$\text{AdC}(xx) \supset \text{AdD}(xx)$	From SC2. Cf. ID ₁ and IIID ₁ . “If something is conceived adequately through itself, and not part of it, this something is its own adequate cause.”
SC9	$\text{AdD}(xx) \sim \text{AdC}(xx)$	From SC7 and SC8. “There is mutual implication between self-causation and self-conception.”

The next twenty theorems (SC₁₀ through SC₂₉) concern the relations that connect causality and understanding to various factors already introduced in chapters 1 and 2.

SC ₁₀	$\text{AdD}(xx) \sim \text{ENPC}(x)$	From ID ₁ . “If something is an adequate cause of itself, then existence belongs to that without which it cannot be conceived, and vice versa.” “That which causes itself cannot be conceived as nonexistent.”
SC ₁₁	$\text{AdC}(xx) \sim \text{ENPC}(x)$	From SC ₁₀ and SC ₉ . “If something can be conceived through itself, then existence be-

longs to that without which it cannot be conceived, and vice versa.”
 “That which is adequately conceived through itself, is such that it cannot be conceived as nonexistent, and vice versa.”

The symbolic versions of the theorems make certain structural relations clear and explicit. When it comes to “translating” them into words, however, a great variety of questions arises. Apart from ambiguities and differences in preciseness, there are important hermeneutical questions involved in the translations. I have not tried to standardize translations. On the contrary, I have tried to exhibit the great range of wordings that suggest themselves. Part of the value of the symbolization derives from the fact that *only* certain structures are made (visually) manifest; that is, certain internal relations between clusters of terms, notions, and theorems.

Exactly analogous pairs of relations to the pair SC₁₀ and SC₁₁ hold with regard to the five predicates -PCNE, ES, -RE, CS, and -RC. We shall refer to them as SC₁₂–SC₂₁. The six predicates were introduced in chapters 1 and 2 as absolutes characterizing God and substance. Thus, ES(*x*) would mean the same as “AdES(*x*),” not “AdES(*x*) or InES(*x*).”

SC ₂₂	AdD(<i>xx</i>) ~ AdL(<i>x</i>)	From SC ₁₀ and SB ₁₀ . “If something is an adequate cause of itself, it is completely free, and vice versa.”
SC ₂₃	AdC(<i>xx</i>) ~ AdL(<i>x</i>)	From SC ₁₁ and SB ₁₀ . “If something is adequately conceived through itself, it is completely free, and vice versa.”
SC ₂₄	InD(<i>xx</i>) ~ -ENPC(<i>x</i>)	From SC ₁₀ . “If a thing is only inadequately a cause of itself, existence does not belong to that without which it cannot be conceived, and vice versa.”

CAUSATION, COGNITION, AND ACTION

SC25	$\text{InC}(xx) \sim \neg \text{ENPC}(x)$	From SC24 and SC6. “If a thing is only inadequately conceived through itself, existence does not belong to that without which it cannot be conceived, and vice versa.” Similar pairs of relations are obtained with regard to PCNE, EA, RE, CA, and RC.
SC26	$\text{InD}(xx) \sim \text{PCNE}(x)$	From SC12. “If a thing is only in part a cause of itself, it can be conceived as nonexistent, and vice versa.”
SC27	$\text{InD}(xx) \sim \text{EA}(x)$	From SC24 and SB6. “If a thing is only inadequately a cause of itself, it is in something else, and vice versa.”
SC28	$\text{InD}(xx) \sim \text{InL}(x)$	From SC22. “If something causes itself only partially, it is only partially free, and vice versa.”
SC29	$\text{InC}(xx) \sim \text{InL}(x)$	From SC28 and SC6. “If a thing is only in part conceived through itself, it is only in part free, and vice versa.”

The next thirteen theorems have to do with activeness, especially the important parallelism between being active and understanding.

SC30	$\text{AdD}(xy) \supset \text{AdG}(xy)$	From generalizing IIID2, first part. “If something adequately causes something, it is adequately active in relation to it.”
------	---	--

SC ₃₁	$H(x) \& AdD(xy) \supset AdG(xy)$	Suggested by IID2, first part. Logically derivable from SC ₃₀ . “If a person is the full cause of something, he is fully active in relation to it.”
SC ₃₂	$AdG(xy) \supset AdD(xy)$	Suggested by generalizing IID2, first part. “If something is fully active in relation to something else, it adequately causes it.”
SC ₃₃	$H(x) \& AdG(xy) \supset AdD(xy)$	Logically derivable from SC ₃₂ . “If a person is completely active in relation to something, he causes it adequately.”
SC ₃₄	$AdG(xy) \sim AdD(xy)$	From SC ₃₀ and SC ₃₂ . “If a thing is fully active in relation to something, it causes it adequately.”
SC ₃₅	$H(x) \& AdG(xy) \sim AdD(xy)$	Logically derivable from SC ₃₄ . “If a person is fully active in relation to something, he causes it adequately, and if he thus causes a thing, he is fully active in relation to it.”
SC ₃₆	$AdC(xy) \sim AdG(xy)$	Suggested by IID2, second part. Logically derivable from SC ₃ and SC ₃₄ . “If something is adequately conceived through something else, the latter is adequately active relative to the former, and vice versa.”
SC ₃₇	$H(x) \& AdC(xy) \sim AdG(xy)$	Logically derivable from SC ₃₆ . “If something is adequately conceived through a person, this person is adequately active relative to it, and vice versa.”

CAUSATION, COGNITION, AND ACTION

SC ₃₈	$CS(xy) \sim AdG(xy)$	From SC ₃₆ . “To understand something through oneself implies being active toward this something, and vice versa.”
SC ₃₉	$InD(xy) \supset InG(xy)$	Suggested by IID ₂ , second part. “If a thing is partly a cause of something, it is partly active in relation to it.”
SC ₄₀	$InG(xy) \supset InD(xy)$	Suggested by IID ₂ , second part. “If a thing is only inadequately active in relation to something, it is only inadequately its cause.”
SC ₄₁	$InG(xy) \sim InD(xy)$	From SC ₃₉ and SC ₄₀ . Based on IID ₂ , second part. “To be partly active in a relation and to be a partial cause mutually imply each other.”
SC ₄₂	$InG(xy) \sim InC(xy)$	From SC ₃₉ and SC ₆ . “If something is only partly active in relation to something, the latter is inadequately conceived through the former.”

The next nine theorems (SC₄₃ through SC₅₁) concern human smallness as a prelude to the assessment of human greatness—a greatness, however, that must share in some important ways with every particular thing.

SC ₄₃	$H(x) \supset EA(x)$	A person is a <i>modus</i> (IIP ₁₀ Cor), and a <i>modus</i> is something in something else. Cf. ID ₅ . “A person is something that is in something else.”
SC ₄₄	$H(x) \supset -AdES(x)$	From SA ₁ and SC ₄₃ . “A person is not something that is totally in itself.”

SC ₄₅	$H(x) \supset CA(x)$	From SC ₄₃ and SA ₁₄ . Suggested by ID ₅ and by the notion of a person as a <i>modus</i> . “A person is conceived through something else.”
SC ₄₆	$H(x) \supset -AdCS(x)$	From SC ₄₅ and SA ₆ . “A person is not conceived totally through itself.”
SC ₄₇	$H(x) \supset PCNE(x)$	From SC ₄₃ and SB ₆ . “A person can be conceived not to exist.”
SC ₄₈	$H(x) \supset -ENPC(x)$	Suggested by IIA ₁ and IID ₂ . Logically derivable from SC ₄₇ and SB ₃ . “It is not so that human existence belongs to that without which a person cannot be conceived.”
SC ₄₉	$H(x) \supset -AdL(x)$	From SC ₄₈ and SB ₁₃ . “No person is totally free.”
SC ₅₀	$H(x) \supset RE(x)$	From SC ₄₇ and SB ₉ . “A person requires something else in order to exist.”
SC ₅₁	$H(x) \supset RC(x)$	From SC ₄₇ and SB ₈ . “In order to be conceived, a person requires the conception of something else.”

All these theorems on the smallness or limitations of human beings presuppose the absoluteness of the dichotomies in part I of the *Ethics*. They also presuppose the cleavage straight under the absolute maximum of a predicate: “being in oneself” and “free” are synonymous with “being completely, absolutely in oneself” and “being completely, absolutely free,” whereas the least bit of being in something else or being a trifle less free than Spinoza’s God immediately pulls a thing down into the region of “being in something else” and “being not free.” In the rest of the *Ethics*, however, the dichotomies of part I are mollified.

In IIP6Dem, it is said that God *acts* through each particular thing. When God expresses himself, he does not do so by means *of*, but *through*, the modes. No other way of expression is mentioned in the *Ethics*. All modes *are* such expressions.

In IIP6Dem, the process of expression may be said to be explained or elucidated by the statement that God *is* and *acts* through particulars. It is an admirable way of formulating the immanence of God. Since God is not different from substance, the activeness of substance is fully contained in, and dependent on, the activeness of modes. Theorems SC52 and SC53 assert something about particular things, not about any thing (*res*) whatsoever. The symbolic form does not take that into account. It could be done by introducing a predicate $\text{Par}(x)$. SC53 would then run as follows: $(x) (\exists y) \text{Par}(x) \supset \text{AdG}(xy)$. For the sake of simplicity I have omitted such a predicate.

SC54	$(x) (\exists y): \text{H}(x) \ \& \ \text{AdD}(xy)$	From SC52. “Every person causes something adequately.”
SC55	$(x) (\exists y): \text{H}(x) \supset \text{AdG}(xy)$	From SC53. “Every person is completely active in at least one relation.”
SC56	$(x) (\exists y) \text{AdC}(xy)$	From SC52 and SC3. “Everything is such that there is at least one thing that is adequately conceived through it.”

IV

Grading Basic Distinctions

Survey D

Freedom: A Matter of Degree

In part I of the *Ethics*, Spinoza introduces a series of predicates: “in itself,” “conceived through itself,” and others. There is no gradation or qualification, but neither are there any explicit attacks on gradualism. In later parts, however, some of the same predicate words express graded predicates, or they appear with other qualifications that rule out the view that they represent absolute dichotomies. In what follows we shall refer to such deabsolutizing as forms of “grading” in a wide sense.

Thus, in IVP59Dem and IVApp31, perfection is graded. Man is capable of increasing his degree of perfection. In IVP73Dem, the expression “freer” (*liberius*) is used. Man is capable of living *freer*, in *greater* freedom.¹ The theorem itself contains the expression “more free” (*magis liber*): “The rational man [*homo qui ratione ducitur*] is more free in a state . . . than alone.” We may also use degree of freedom to reflect variations in relation to circumstances: “[I]nsofar as he endeavors to live in freedom, he desires to order his life according to the general good. . . .”

In *Letter 21*, there is another occurrence of grading: “The external factor is the element of coercion, the inner factor is the factor of freedom—the more the latter predominates, the more free we are [*eo liberiores simus*].” In *Notes to the Theological-Political Tract*, we find several occurrences: “In whatever state a human being may be, he can be free. For certainly, man is to that extent free, to which he follows reason [*eatenus liber est, quatenus ratione ducitur*]. . . . [T]he more man is led by reason, that is, the more he is free . . .” (*Adnotatio* 33). Similar occurrences are found in the *Political Treatise*.

GRADING BASIC DISTINCTIONS

In parts III, IV, and V of the *Ethics*, the free man is sometimes characterized by words reserved in part I for God and substance. One might infer from this that the free man is a kind of transcendental ideal, never to be reached. But from many propositions it is clear that there are free men. As regards the basic *in se* predicates, several are applied to the free man, and many other predicates linked to them by equivalences are used in prominent theorems.

From the mutual implications of theorems on freedom and theorems on being in oneself, having power, being adequate cause, and so on, the grading of freedom implies grading of the other *in se* and *in alio* predicates.

Let us for a moment consider what would follow if we make the assumption that in the later parts of the *Ethics* Spinoza uses the absolutist dichotomies of part I. The free man is characterized by his “acting out of the laws of his own particular nature” (*ex legibus propriae naturae agere*; see IVP24Dem), and by his “doing what follows necessarily from his nature” (cf. IVP24, IVP26Dem). The free man acts out of virtue: that is, he performs actions that can be understood from the laws of man’s nature alone. This implies that the free man can be adequately conceived by himself, which in turn makes man, according to Spinoza’s own teaching in part I, a substance. Ultimately, this implies that each man is God himself. The famous prelude of the fifth part (*Transeo tandem ad alteram Ethices partem . . . , quae ad Libertatem ducit*) could be interpreted as a prelude to a treatise on how to become God. Part V would have to be interpreted as a description of how to reach *absolute* freedom by a sudden metaphysical jump from absolute slavishness (lack of freedom) to the divine level of liberty.

These consequences of extending the absolute dichotomies of part I into parts IV and V are clearly un-Spinozistic. Man is neither an absolute slave nor God. Spinoza’s description of the free man can be made consistent with man being different from God and substance by introducing three levels of freedom, power, and other characteristics that are predicated both of God and of men. The levels can be conceived as that of absolute absence of a predicate, limited possession of it, and absolute, unlimited presence. Thus, there is a grading involved. Our reconstruction makes use of *the principle of grading the basic predicates*.

Men participate more or less in freedom, or they are more or less free, because they are more or less reasonable. The more we go into the details of

Spinoza's descriptions of free and unfree man, the more dimensions we see of this freedom. Not only is the simple dichotomy of free versus unfree incompatible, but there are also several dimensions to be distinguished in defining each level.

Tentative definition: a predicate shall be said to be graded if it holds more or less, in some but not all respects, in some but not all situations, sometimes but not always, partially but not totally, in some relations but not in all. The terms *graded* and *in degrees* as used here are thus a collective name for a family of related properties. Gradedness has, *prima facie*, at least four dimensions.

Let us take the case of reasonableness. To act out of virtue is to be led by reason (*ex ductu rationis vivere*), and grading is quite natural here. We may in the time dimension be sometimes, not always, led by reason; we may in certain kinds of situations not at all be thus led—in some relations, not in all. On comparing two people in the same narrow kind of context, we might say that the one acts completely, fully, adequately rationally, the other only inadequately. In a particular context a person may exhibit no trace of irrationality. This suggests that we may also say he acts completely freely in that context, and that he is an adequate cause of his own action. The summing up of irrationality and rationality in one measure is, however, out of the question.

If on being given a definite task at a definite moment in a definite social setting two people act in this same context, we might on the basis of their performance conclude that the one acts more rationally than the other. In the next moment, though, a second act has to be performed, and our judgment might be the opposite; the less rational in the first context acts more rationally in the second. Which person scores best when both contexts are counted together? The principle of grading does not presuppose that there is a rule here. The principle of grading is not a *principle of quantification*.

Similar grading applies to a number of other predicates; for instance, to the predicate "conceive through itself." A conception may be more or less complete, adequate, profound, lively, and dynamic. It may be more or less consistent through time, through repeated applications, or through applications in different situations; and the extent of the relations in which something is conceived through itself may vary. Further, there is a progression from inadequate, indistinct, confused, and fragmentary conceptions to

GRADING BASIC DISTINCTIONS

adequate, distinct, clear, and comprehensive conceptions. This cannot but interact with the level of “understandability through oneself” and of “extent of being in oneself.” The latter expression is used in IIP6.

Already in part I the important but difficult expression “as” or “insofar as” (*quatenus*) introduces a bridge between opposites. God appears “modified,” that is, manifested in particular things. In the long note IP15Sch, Spinoza talks about water “as substance” (*aqua quatenus substantia*). The term *quatenus* is a central one in Spinoza’s system but extremely difficult to comprehend in its several hundred occurrences. We take it to imply a gradation in the very wide sense introduced. A basic idea in its use is this: something, *x*, may be classed as a *y* and not a *z quatenus t*, whereas the same *x* may be classed as a *z* and not as a *y quatenus u*. Or, in the old *esse* terminology of Spinoza: “*x* is *y quatenus t*, and *z, quatenus u*.”

The widest, and therefore best, translation and interpretation of *quatenus* in these contexts seems to be “in relation to.” “Something *x* is *y* and not *z in relation to t*.” Very little is gained by using this expression; nearly all is left to the analysis of each particular occurrence of *quatenus*.

Another important bridge from absolutism to gradualism is furnished by an already mentioned class of expressions—“God considered as . . . ,” “God as affected by . . . ,” and so on—which leads toward a realistic concept of the immanence of God and substance in the world of particulars (cf. IIP9, IIP9Cor, IIP11Cor: “. . . God, not as infinite, but insofar as [*quatenus*] he is expressed by the nature of the human mind, or insofar as he constitutes the essence of the human mind, . . .”). The love of the transcendent God as conceived in the three great monotheistic religions makes sense, but love of a purely immanent God is something so different that to use the term *God* may be considered to be misleading. What Spinoza tries to convey is, at least in the seventeenth century, scarcely conveyable through using that term. Through the *quatenus* technique, Spinoza renders the terms *God* and *substance* avoidable in the exposition of the system. Their elimination, however, signifies a vast reduction in the persuasive, positive evaluation of the cosmos or of “what there really is.” On the other hand, the exposition without the terms gains intellectual clarity and acceptability in our century.

The important theorem on self-preservation (IIP6) has a grading: “Everything, insofar as it is in itself [*quatenus in se est*], strives to uphold it-

self in its being.” Later, gradation is presupposed when Spinoza discusses how man arrives at higher levels of perfection through joy. Joy is transition “from smaller to greater perfection” (III AffD2) and, therefore we may add, from smaller to greater reality (IID6). Also, how is he able to proceed from the first to the second and third kinds of knowledge? A grading of the quality of knowledge is made use of explicitly or at least implicitly. Of considerable importance is the grading of inadequacy of conceiving. Taking IIP29Sch as our point of departure, we note that a measure of adequacy is already introduced when we perceive many things at once. The more we perceive at once, the better. The contrast elaborated by Spinoza in IIP29Sch is that between perceiving a thing in complete isolation and perceiving it in relation to many others:

I say expressly that the mind has not an adequate but only a confused knowledge of itself, its own body, and of external bodies . . . whenever it is determined . . . by the fortuitous play of circumstance, to regard this and that; not at such times as it is determined . . . by the fact of regarding several things at once, to understand their points of agreement, difference, and contrast.

Although there are infinitely many things, man is barred from seeing all in their mutual relations. These are infinite for each thing. Thus, complete or absolute adequacy is out of the question. It is a prerogative of the infinite intellect, that is, of something not existing separately from anything whatsoever. We shall nevertheless assume that man can reach *high degrees* of adequacy perceiving many things in many relations.

Grading “Being in Itself”

Every particular, singular, concrete, finite thing is to a certain extent in itself and to another degree in something else. Similar qualifications apply, then, to all the equivalent properties. The resulting concept of a “particular, singular, concrete, finite thing” is similar to Spinoza’s concept of *res particularis* and *res singularis*. There are some differences, but in what follows, we do not take account of them.²

The above delimitation of a thing-concept is meant to furnish an answer to the questions “What kinds of ‘things’ are the *x*’s in expressions such

GRADING BASIC DISTINCTIONS

as ‘ x is more free than y ’ and ‘ x is more in itself than y ’?” “What is the range of the predicate?” The answer we give is that the x ’s are particular, singular, concrete, finite. Among such things, human beings, or better, *persons*, are our primary concern; they make up the “primary field of application.” We shall find evidence, however, that the fields are wider than that. In our reconstruction we shall conceive the things (*res*) to be *living* things. Persons as wholes are particulars rather than minds, human bodies, intellects, subjects, or humanity. It is our contention that Spinoza is basically trying to reach knowledge of particulars and to transcend mere knowledge of kinds, *species*. He wishes us to move from the first and second ways of knowing to the third, but not through the elimination of those kinds.

The technical terms *in itself* and *in something else* introduced in chapters 1, 2, and 3 express dichotomies, not graded magnitudes. From now on, these terms are viewed as graded. We retain the terms in our reconstruction but change their use. Rereading chapters 1–3, we shall now take the *in itself* terms as expressions of the absolute maximum of a graded property. Thus, we take *in itself* in chapters 1–3 to mean the same as “completely (wholly, absolutely) in itself”; *conceived through itself* to mean “conceived completely through only itself”; and *does not require something else* to mean “does not require anything whatsoever under any circumstances whatsoever.” We take the *in something else* terms as used in chapters 1–3 to be negations of the *in itself* terms, not opposites. Thus, *in something else* stands for “not completely (wholly, absolutely) in itself,” and not for “completely, absolutely not in itself” or “totally in something else.”

A particular thing is always to a certain extent, however small, in itself, never totally in something else. This is not said explicitly anywhere in the *Ethics*, but it fits the total text better than the opposite assumption. Evidence of this will be referred to at appropriate places. Since Spinoza himself constantly uses all four expressions “in itself,” “not in itself,” “in something else,” and “not in something else,” we have from the very beginning avoided the assumption that “not in itself” is identical with “in something else.” There is, however, no positive evidence that there is a difference, and from now on we assume that there is none.

We shall now offer a short, abstract, philosophical justification for the project of grading. The God of Spinoza, like the God of many other philosophers, expresses himself in infinitely many things in infinitely many ways.

These things, the particulars (*res particularis*), exist, have existed, or will exist, if we take *exist* to imply having a separable existence from God. However, a basic metaphysical idea of Spinoza is *the immanent God*. God's essence and power are completely expressed through the modes—nothing transcendent remains. Nothing exists as a separable being. The usual meanings of “x expresses itself through y” break down. An author or poet expresses himself through his poems, but *something* is left over when we strip him of his poems. Without modes, that is, when God is stripped of his expressions, there is no God.

In at least one important respect, therefore, God is dependent on modes. Modes are in God (*sunt in Deo*) and God is in himself (*est in se*), but nevertheless God is nothing apart. Therefore, the “*being* in something else,” insofar as it is characteristic of the relation between modes and God, is nothing but expressiveness of something. Perhaps one may say the immanent God does not exist but “is,” in the traditional scholastic terminology.

There is only one substance, according to Spinoza, namely God. He could have added “Substance is the only God.” I might add “To seek God is devotedly to seek maximum increase in substantiality.” Spinoza himself warns us not to take seriously any other statement about God than that he has extension and thought as attributes. This does not imply that God has a definite extension, finite or infinite, or that he is a definite thought. In that case we would have to assume the existence of God as something apart from other “existents,” and the principle of immanence would be lost.

These reflections are relevant here because they render it justifiable metaphysically to introduce a gradation of substance: *substantiality*. Substance is completely *in se*. The grades of being *in se* we might conceive as degrees of substantiality. It is better, though, to leave out such a term; it does not have the importance it had in the time of Descartes, Spinoza, and Leibniz. We shall leave out substance as a separable entity on a par with particular things and retain a property the infinite maximum of that which is named “being in itself” in Spinoza's *Ethics*, part I, and in chapters 1–3 of this work.

Our substitution of degree of substantiality for substance is not necessarily inconsistent with Spinoza's claim that God is not only an *ens rationis* but also an *ens reale*. The concept of a ‘whole’ or ‘concrete universal’ as explicated by Wolfson (1961, vol. 1: 325 ff.) is consistent with our idea of a maximal, infinite degree of substantiality. This can only belong to the whole (in

GRADING BASIC DISTINCTIONS

a certain metaphysical sense). The concept of such a maximum may be considered a clarification or “analysis” of the notion of whole.

Spinoza’s way of discussing substances, as, for instance, when he argues that there cannot be several substances, suggests that substances have a thing status rather than a property status. If, however, we use another formulation and substitute the term *maximal substantiality* for *substance*, saying that there cannot be several different maximal substantialities, Spinoza’s way of putting it makes good sense when applied to the text: there can be only one maximal substantiality. There may be a bunch of very closely related properties, such as being perfectly in itself, requiring nothing else to exist, being perfectly free, and so on, all with the same maximum.

The ultimate justification of a shift from substance as something thing-like to substantiality as a property can only be in terms of a shift in emphasis away from the particular theologico-philosophical problems of Spinoza’s time. The grading of “requirements for something, x , in order to exist” may be conceived as having to do with the many things required or the status of each required thing. A similar differentiation may be made in relation to some of the other predicates such as “conceptions required in order that x may be conceived” and “other concepts involved in the concept of x .”

At first glance, the following two basic predicates might seem ungradable: “can be conceived as nonexistent” and “existence belongs to that without which something cannot be conceived.” However, they are scarcely less gradable than the predicate “free” when interpreted in full context, and to give up their grading would, because of the intimate interrelations of properties, create vast difficulties for grading other basic predicates. If something can be conceived as nonexistent, one may ask how many other things are lacking in order to ensure its being inconceivable as nonexistent. Or what status do those things have? The superbly free man may be said to require less than the one who is not that free. A similar gradation is conceivable in relation to the other existence predicates, but scarcely without special difficulties.

To show the implications of grading more clearly, we shall now state a few graded theorems corresponding to the theorems of chapters 1, 2, and 3. The graded theorem corresponding to an ungraded theorem, A_n , where n is a number, is named Ag_n —where “g” stands for “graded.” Thus, the graded theorem Ag_1 corresponds to the ungraded theorem A_1 of chapter 1.

- Ag1 That thing which is, is either totally in itself or partly in something else, but never totally in something else.

Instead of the word *partly* we might use *more or less, to some degree, in some ways, in some relations, in some interactions, in some respects, conditionally, in varying nonmaximum degrees*. We do not consider this wide freedom of choice to be ultimate. Further penetration into the subject of grading must be expected to narrow down the range of adequate topological predicates.

- Ag2 That which is totally in itself is that which does not require anything else other than just itself in order to be.
- Ag4 That which is, must be totally in itself if it cannot be partly in something else.
- Ag6 That which is, is totally and adequately conceived through itself alone, or partly by something else.
- Ag7 That which is totally and adequately conceived through itself is that which is such that its concept does not require any other concepts whatsoever in order to be formed.
- Ag16 That which is, more or less requires other things in order to be, or does not require any such things whatsoever.
- Bg1 Something cannot at all be adequately conceived as nonexistent, or can be so conceived conditionally or in part.

For example: a person *as a whole* is in something else and can be conceived as nonexistent—at any time under any conditions; but when that person adequately “causes something outside or inside himself” (IID2), something inside or outside him can be wholly and totally, that is, adequately, conceived through him. *In this relation he cannot be adequately conceived as nonexistent.*

- Bg11 If something can conditionally or to some extent adequately be conceived as nonexistent, it is to that extent unfree, and vice versa.

GRADING BASIC DISTINCTIONS

- Bg12 If something cannot in any relation be adequately conceived except as existent, it is totally free, and vice versa.
- Cg7 If something is the complete, in all relations, adequate cause of itself, it is completely and clearly understood through itself, and vice versa.
- Cg23 That which is in all relations conceived by itself, is free in all relations.
- Cg32 If a person is totally active in relation to something, he causes it adequately.
- Cg43 A person is to some extent in something else.
- Cg44 A person is not totally in himself.
- Cg45 A person is to some extent conceived through something else.
- Cg46 A person is not completely conceived through himself.
- Cg49 A person is not totally free.

Power

There is an ever-increasing consensus among the commentators on Spinoza that his philosophy should be considered primarily as a dynamic power philosophy. Power (*potentia*) is also at the heart of this theory of affects. The affects of an organism are defined in terms of the transitions in its power relations. These transitions, which consist of increases and decreases in the power of the organism, constitute the basis for the positive and negative sentiments, and for the desires which originate in these sentiments. The transitions may be partial or total, depending on whether they are related to some parts of the person (or organism), but not to the whole person, or to some, but not all of his relations to other persons and to nature in general; or whether they concern the person and his relations as a whole.

(Wetlesen 1969: 117)

These words by Jon Wetlesen are well suited as an introduction to the assimilation of power into our conceptual structure.

From IP11Dem3, IP11Sch, and IVP4Dem we infer that every infinite being is more powerful (*potentiora*) than any finite being. Spinoza expressly

states that it is absurd to hold that finite beings are more powerful than infinite ones.

In Spinoza's terminology, to be able to exist is a form of being positively able to do something. His term *potentia* is clearly very broad, a substantivation of the common Latin verb *posse* ("to do" and "to be able to").

"To have the power to" is not as broad as "to be able to," since to be able to not-to-exist (*posse non existere*) is taken by Spinoza to be a form of powerlessness, not a form of power, in spite of being a form of *posse*. In short, a form of "can" (*posse*) in the broadest sense may sometimes be a form of "inability" (*impotentia*). Spinoza distinguishes several forms of power. His terminology is rich at this point. He uses at least six expressions: "*potentia*," "*potentia agendi*," "*potentia cogitandi*," "*potentia cognoscendi*," "*potentia imaginandi*," and "*potentia intelligendi*." We need an inclusive concept covering all these species and we shall designate it simply by "power" (*potentia*). An increase in power will be said to take place only if there is an increase in at least one form of power, and no decrease in any. Similarly, a decrease will be said to take place if there is a decrease in at least one form, and no increase in any other.

If the power of something, *A*, reaches an absolute maximum, we stipulate that its activity (*potentia agendi*) must be at an absolute maximum. When Spinoza uses the simple terms *potentia* and *potestas*, we take them to be synonymous with *potentia agendi*, if the context does not clearly suggest something different. This means, according to IID2, that *A* cannot but be adequate as a cause, and being supremely active will be an adequate cause of anything whatsoever. We are therefore entitled to equate absolute maximum of power with being *causa sui*. Being *causa sui*, in turn, implies having the rest of the in-itself properties. The fundamental Spinozistic postulate of the immanence of God has as a consequence that such an absolute, all-embracing power cannot *exist* apart. But it can, and must, *be*. "Things," or more generally, anything *existing*, will have a power less than infinite (in all respects imaginable), that is, less than the theoretical maximum. Further, we are entitled to equate an increase in power with an increase in activeness and therefore in adequacy as cause. This links the notion of increase of power with that of increase in level of in-itself, or freedom, and of the other basic in-itself properties.

To the various forms of power there will correspond various forms of the other in-itself properties. A stipulation, however, will be applied to

GRADING BASIC DISTINCTIONS

each case: a change is to be reckoned as an increase in the many-dimensional relations only if there is no decrease in any of the dimensions. There is, for example, only an increase in freedom in general if there is no decrease in any form of freedom. (It would raise too many problems here to ask for a measure that would allow one to compare an increase in one dimension with a decrease in another.)

Suppose a person H at time t_2 conceives something with a higher degree of adequacy than before, at time t_1 . Does this imply that he, in the terminology of Spinoza, conceives it better out of, by means of, or through himself? The situation of H at time t_2 is such that the degree of “conceivability through himself” or “capacity of understanding [*potentia intelligendi*] through himself” is raised. This capacity may be taken to be equivalent in its manifestations to the *joint* capacity of being active and of understanding.

In God, being absolutely in itself, the various capacities are symbolically united in one. In other words, at the theoretical maximum or conceptual level, the capacities are united. Thus, according to IIP7Cor, God’s thinking power (*cogitandi potentia*) is the same as his power of acting (*actuali agendi potentia*). In human beings this unity cannot be achieved. We shall assume, however, a mutual implication between an increase in an individual human being’s ability to conceive particulars A , B , and C and that individual’s active relations toward A , B , and C .

If y is conceived (i.e., capable of being conceived) through x , the question arises, Capable of being conceived by what kind of beings? The primary, but not ultimate answer in the context of the *Ethics* is “human beings.” If, now, x is a human being and therefore y is conceived through x , I assume that x is theoretically capable of conceiving y . We need not go into the relation of capability to actuality here, but it would be awkward to have to assume that if y is conceived through x , and x is a human being, y must continuously be conceived by a human being.

If we say that total freedom is a property of that which is totally in itself, the formulation may be misleading, because it suggests a difference at the extensional level between the totally free and the totally in itself. The totally free *is* the totally in itself, and vice versa. This does not contradict the fact that there are in the system two different *entia rationis* (conceptual constructions), one expressed by “total freedom” and the other by “being

totally in oneself.” Taking into account how Spinoza characterizes the function of *ratio*, we conclude that the *entia rationis* have all the functions to assist in increasing freedom. To do something that is not conducive to this or is neutral in relation to the ultimate goals is not rational.

There is a kind of democracy among the in-itself predicates insofar as any one of them can, if one wishes, be substantivated and any other one can be used as a predicate in relation to the substantive clause. Thus, one may say “The totally self-conceived is totally in itself” or “The totally in itself is totally self-conceived.” The different wordings should not mislead one into postulating various (independent) dimensions of substantiality at the extensional level.

This may bring us to the question of whether two different things could both have the absolute maximum of substantiality. This is the question of whether there is more than one substance. First, there cannot be two substances of different essence or nature. That would imply that we perceive substance as a member of a class. This is ruled out by substance being conceived through itself and not through any class property. Restated, what is conceived through itself and not through a class property *is* substance.

Second, the thought of two different substances with the same essence or nature is absurd since, being separated from each other, they would have to be in something else, as for instance two only numerically different coins are in a box, or two only numerically different thoughts (one “repeated” thought) are in one mind. Since substance is not in something else, the thought of two or more substances is absurd. Since the essence of substance implies existence, there is one and only one substance. Any other conclusion somehow implies a critique of the very notion of “conceived through itself” and the other in-itself and in-something-else terms.

The above argumentation is, I think, in substantial agreement with Spinoza’s trend of reasoning in part I from the beginning to the eighth proposition. Of special importance is the second half of the scholium that refers to IP7 (misnamed IP8Sch2 by Spinoza).

Survey D Using Symbols

It is convenient to attach subscripts to our previously introduced predicate symbols in order to symbolize gradedness. We shall do this, but it must

GRADING BASIC DISTINCTIONS

also be borne in mind that some of the graded properties to be introduced now are, strictly speaking, new properties, not properties previously introduced and now being graded.

The symbolic formulations of chapters 1, 2, and 3 will be retained, and the basic in-itself predicate symbols in those chapters will be used, as already mentioned, to express the absolute maximum of a property. Thus, “being in itself,” as it occurs in chapter 1, is from now on taken to mean “being totally, absolutely in itself” or “being in itself in all relations.”

On the other hand, if we take “being in something else” and view the absolute maximum of this property to mean “being totally, absolutely in something else,” then many theorems of chapter 1 would have to be reformulated. According to our interpretation of Spinoza’s system, no particular thing is totally, absolutely in something else. Particulars are all in God, taken absolutely (*quatenus absolute*), but not totally in God, as modified (*quatenus modificatus*).

We shall therefore take the in-something-else predicate symbols of chapters 1–3 to refer to the simple negation of the in-itself predicates in their absolute sense. Thus, that which is *not* totally in itself will be said to be in something else. To be in something else is thus perfectly consistent with being partly in itself.

Before going into our present subject of symbolization, I have to ask for a substantial amount of tolerance from readers who still do not appreciate the use of symbols in surveying conceptual structures. From now on, the theorems are not listed separately in plain language but are found under each symbolic formulation as a sort of translation. Furthermore, what might perhaps be more irritating, some theorems are offered that say practically nothing: they have some function only within the increasingly complex machinery of derivation of the more important items.

For the general trend of our argument and the interpretations involving grading, it is unnecessary to inspect the paragraph below that begins, “More formally . . .,” or to read the detailed proof of SD6, p. 70. Why, then, burden the exposition with these things? Because for anyone interested in the question of whether the symbolic version can be made logically unobjectionable, these formal details are of some importance. Among theorems SD1 through SD45, at least the following are of more than formal significance: 2, 2a, 15, 15a, 16a, 17, 24a, 33, 34, and 40.

New Symbols:

$d(y)$ y is a degree

Let $d(y)$ mean that y is a degree of such a kind that there are only three different degrees: $y = 0$, $0 < y < \infty$, or $y = \infty$. If y is attached to a predicate symbol, this means that the predicate is valid to degree y . Thus, $L_y(x)$ reads “ x has freedom of degree y .” $L_\infty(x)$ reads “ x is infinitely free” or, rather, “ x is free to the theoretically maximal degree,” which can also be recast as “ x is totally free” or “ x is free in absolutely all relations.” This was expressed by our old symbol $L(x)$ in chapters 1–3, but from now on is written as $L_\infty(x)$.

More formally, we can introduce sets of four abbreviations and one axiom related to each syncategormatic symbol:

$L_0(x)$ Def $(\exists y) (d(y) \ \& \ y = 0 \ \& \ L_y(x))$

$L_{>0}(x)$ Def $(\exists y) (d(y) \ \& \ y > 0 \ \& \ L_y(x))$

$L_{<\infty}(x)$ Def $(\exists y) (d(y) \ \& \ y < \infty \ \& \ L_y(x))$

$L_\infty(x)$ Def $(\exists y) (d(y) \ \& \ y = \infty \ \& \ L_y(x))$

$(y) [(d(y) \ \& \ L_y(x)) \supset \neg(\exists z) (d(z) \ \& \ z \neq y \ \& \ L_z(x))]$

Where “Def” stands for “shall be taken to mean” or “means the same as.” The above set, the L-set, relates to freedom. Exactly analogous sets relate to ES, CS, RE, RC, PCNE, ENPC, and so on, or, in short, to each predicate of the in-itself or ES class of predicates introduced in chapters 1 and 2. Further, there is a set related to power, P. In what follows, we assume the resulting nine axioms and thirty-six abbreviations introduced. We consider the predicates EA and CA to be covered by the negations -ES and -CS.

The three degrees may be interpreted as complete absence, presence at a maximum, and a level in between complete absence and presence at a (theoretical) maximum. Thus:

$ES_y(x)$ x is to extent y , in itself

$EA_y(x)$ x is to extent y , in something else

GRADING BASIC DISTINCTIONS

Giving y particular values, we have:

- $ES_{\infty}(x)$ x is totally, absolutely in itself
 $ES_{>0}(x)$ x does not totally lack being in itself, and so on

Using the interval $(0, \infty)$ instead of $(0, 1)$ has some consequences that should be mentioned. No finite number is greater than any other, compared to ∞ ; thus, we have no justification for saying “N. N. has reached a high level of freedom.” But levels can be compared: “N. N. has now reached a higher level”; no finite number is near ∞ , so we cannot say “N. N. has reached a level near that of God,” but we might say “N. N. has come nearer to the level of God, letting it be understood that nothing more is meant than that he has moved along a line—not away from, but toward—the level of God.” The use of ∞ stresses the “transcendence” of that which is *completely* in itself, that which is *completely* conceived through itself, and so on. There is a lack of continuity between the not complete and the complete corresponding to the discontinuity between a finite and an infinite set of numbers.

If, on the other hand, the interval $(0, 1)$ were to be used—that is, a closed interval—we would, in principle, be able to indicate a finite number, for instance 0.01 as a measure of the distance between the freedom of God and that of a very free man. A human being might be said, without any qualification or comment, to have come near the level of God. This would introduce difficulties in the system. According to Spinoza, it is essential that man cannot be God, that no particular thing can be substance. There is a logical or categorical difference between God and man. God does not even exist—in the same way as man.

Other New Symbols:

- $P(xy)$ x has adequate or inadequate power in relation to y
 $P_g(x)$ x is powerful to the degree “ g ”
 $P_{in}(x)$ x increases its power, partially or totally
 $P_{de}(x)$ x decreases its power, partially or totally
 $ES_{in}(x)$ x increases its level of being in itself
 $D_{in}(xy)$ x is increasingly weighty as cause of y

Survey D

First, we consider grading “being in itself”:

$$\text{SD1} \quad (x) (ES_{>0}(x) \& EA_{<\infty}(x)) \quad \text{from SC54 and IP36}$$

Or, not using the abbreviations:

$$\text{SD1a} \quad (x) (\exists y) (\exists z) [d(y) \& d(z) \& o < y \& z < \infty \& ES_y(x) \& EA_z(x)]$$

The formula SD1 may be read: For all x , it holds that x is in itself to a degree greater than zero and in something else to a degree less than infinite. Or, for all things (that may exist), it holds that they are to a degree smaller than the theoretical maximum in something else. Or, for every particular thing, it holds that it is to some extent in itself and not totally in something else. Or, for every existing thing, it holds that in some, but not in all relations, they are in themselves. The wide margin of readings does not reflect a belief that these differences are completely unimportant, but that differences are not taken into account in the symbolic version. They are not essential to the explication of basic structures of the system.

SD2	$(x) ES_{>0}(x)$	From SD1. “Everything is to some degree in itself.”
SD2a	$H(x) \supset ES_{>0}(x)$	From SD2. “Human beings are to some extent in themselves.”
SD3	$(x) EA_{<\infty}(x)$	From SD1. “Everything is less than completely in something else.”
SD4	$ES(x)$ in chapters 1–3 $\underline{\text{Def}} ES_{\infty}(x)$	“From now on $ES(x)$, as occurring in chapters 1–3, shall be taken to mean the same as $ES_{\infty}(x)$.”
SD5	$EA(x)$ in chapters 1–3 $\underline{\text{Def}} EA_{>0}(x)$	“From now on $EA(x)$, as occurring in chapters 1–3, shall be taken to mean the same as $EA_{>0}(x)$.”

GRADING BASIC DISTINCTIONS

SD6	$\neg ES(x)$ in chapters 1–3 $\sim ES_{<\infty}(x)$	From SD2 and SD4, and the axiom pertaining to ES. (That is, the ES-axiom as part of the ES-set. Cf. pp. 67–68.) “If it is not the case that something, x , is totally in itself, then it is less than totally in itself, and vice versa.”
-----	--	--

Proof of SD6 in detail:

1. $(\exists y): d(y) \ \& \ 0 < y \ \& \ ES_y(x)$ from SD2
2. $d(y_1) \ \& \ 0 < y_1 \ \& \ ES_{y_1}(x)$ from (1)
3. $\neg(\exists y): d(y) \ \& \ y = \infty \ \& \ ES_y(x)$ hypothesis: $\neg ES(x)$
4. $\neg d(y_1) \vee y_1 \neq \infty \vee \neg ES_{y_1}(x)$ from (3)
5. $d(y_1) \ \& \ 0 < y_1 < \infty \ \& \ ES_{y_1}(x)$ from (2), (4), and property of “d”
6. $(\exists y): d(y) \ \& \ y < \infty \ \& \ ES_y(x)$ from (5)
7. $\neg ES_{\infty}(x) \supset ES_{<\infty}(x)$ from (3) and (6)
8. $\neg ES_{<\infty}(x) \supset ES_{\infty}(x)$ from axiom pertaining to ES
9. $\neg ES_{\infty}(x) \sim ES_{<\infty}(x)$ from (7) and (8)
10. $\neg ES(x) \sim ES_{<\infty}(x)$ from (9) and SD4

In what follows, the proofs of each theorem are not spelled out in detail.

SD7	$EA(x) \sim ES_{<\infty}(x)$	From SD6 and SA1. “If something is in something else, it is less than totally in itself, and vice versa.”
SD8	$\neg ES_{\infty}(x) \sim EA_{>0}(x)$	From SD5 and SA1. “If something is not totally in itself, it is to some extent in something else, and vice versa.”

SD9	$\neg EA_{<\infty}(x) \sim EA_{\infty}(x)$	From SD3 and the axiom pertaining to EA. “If something is not less than completely in something else, it is completely in something else, and vice versa.”
SD10	$\neg(\exists x) EA_{\infty}(x)$	From SD3 and SD9. Holds even for the narrower concept of ‘being’ in general, namely ‘existing’. “Nothing is completely in something else.”
SD11	$(\exists x) ES_{\infty}(x)$	Suggested by ID6 and IP11. “There is something that is completely in itself.”
SD11a	$(x)(y): ES_{\infty}(x) \& ES_{\infty}(y) \supset x = y$	Suggested by IP7, IP7Dem, and IP8Sch2. “There is one and only one thing that is completely in itself” or “What is totally in itself is unique.”
SD12	$\neg EA_{>0}(x) \sim EA_0(x)$	From SD3 and the axiom pertaining to EA. “If something is not to any degree in something else, it is not at all in something else, and vice versa.”
SD13	$ES_{\infty}(x) \sim EA_0(x)$	From SD11 and SD12. “If something is totally in itself, it is in no way in something else, and vice versa.”

Grading “Conceived Through Itself”

SD14	$(x)(CS_{>0}(x) \& CA_{<\infty}(x))$	From SD1 and SA13. “All things taken one at a time are to some extent conceived through
------	--------------------------------------	--

GRADING BASIC DISTINCTIONS

themselves and are less than completely conceived through something else.”

Or, without using abbreviations:

SD14a	$(x) (\exists y) (\exists z) [d(y) \& d(z) \& 0 < y \& z < \infty \& CS_y(x) \& CA_z(x)]$	
SD15	$(x) CS_{>0}(x)$	From SD14. “Everything is conceived to some extent through itself.”
SD15a	$H(x) \supset CS_{>0}(x)$	From SD15. “Every human being is to some extent conceived through himself.”
SD16	$(x) CA_{<\infty}(x)$	From SD14. “Everything is less than completely conceived through something else.”
SD16a	$(x) C_{>0}(xx)$	From SD15. “Everything is to some extent conceived through itself.”

This theorem makes explicit that the adequate understanding of something cannot proceed *completely* in terms of something else. A “golden mountain” cannot be conceived *completely* from the two concepts ‘golden’ and ‘mountain’ if a golden mountain *exists* as a particular thing. Similarly, an individual cannot be adequately conceived by reference to social rules “governing” his society and not created by himself. Nor can an individual mouse be adequately conceived solely in terms of the “instincts” of mice in general. The individual differences of mice in a mountain hut are obvious.

SD17	$(x) D_{>0}(xx)$	From SD16a and SC6. “Everything is to some extent its own cause.”
SD18	$CS(x)$ in chapters 1–3 $\underline{\text{Def}} CS_{\infty}(x)$	Suggested by SD4 and SA13. “From now on $CS(x)$ in chapters 1–3 is to mean the same as $CS_{\infty}(x)$.”

SD19	CA(x) in chapters 1–3 Def $CA_{>0}(x)$	Suggested by SD5 and SA14. “From now on CA(x) in chapters 1–3 is to mean the same as $CA_{>0}(x)$.”
SD20	$\neg CS_{\infty}(x) \sim CS_{<\infty}(x)$	From SD15 and SD18, and the axiom pertaining to CS. “If something is not conceived totally through itself, it is conceived less than totally through itself, and vice versa.”
SD21	$CA_{>0}(x) \sim CA_{<\infty}(x)$	From SD20 and SA6. “If something is to some extent conceived through something else, it is nevertheless not conceived in that way in all relations, and vice versa.”
SD22	$\neg CS_{\infty}(x) \sim CA_{>0}(x)$	From SD19 and SA6. “If something is not in all relations conceived through itself, it is in some relations conceived through something else, and vice versa.”
SD23	$\neg CA_{<\infty}(x) \sim CA_{\infty}(x)$	From SD16 and the axiom pertaining to CA. “If something is not less than completely conceived through something else, it is conceived totally through something else, and vice versa.”
SD24	$(\exists x) CS_{\infty}(x)$	Suggested by SD6 and ID3. “There is at least one thing that is completely conceived through itself.”
SD24a	$(x)(y): ES_{\infty}(x) \& CS_{\infty}(y) \supset x = y$	From SA13, SD19, and SD11a. “There is one and only one thing that is completely conceived through itself.”

GRADING BASIC DISTINCTIONS

SD25	$\neg CA_{>0}(x) \sim CS_{\infty}(x)$	From SD22 and the axiom pertaining to CA. “If something is not to some extent conceived through something else, it is totally conceived through itself, and vice versa.”
SD26	$CS_{\infty}(x) \sim CA_0(x)$	From SD25. “To be conceived completely through itself is to be in no way conceived through something else.”

Grading Requirements for “Being” and “Being Conceived”

SD27	$(x)(\exists y)(RE_y(x))$	Suggested by SD3 and SA3. Logically derivable from SD29. “For all things it holds that there is a grade that indicates the extent to which they require something else to exist.”
SD28	$EA_{<\infty}(x) \sim RE_{<\infty}(x)$	Suggested by SA14. “If something is less than totally in something else, it requires in less than all respects something else in order to exist, and vice versa.”
SD29	$(x) RE_{<\infty}(x)$	From SD3 and SD28. “Everything does in less than all respects require something else in order to exist.”
SD30	$\neg RE(x)$ in chapters 1–3 $\stackrel{\text{Def}}{=} RE_0(x)$	“From now on the expression ‘not require anything else to exist,’ as it occurred in chapters 1–3, shall mean the same as ‘ x requires to zero degree something else to exist.’”

SD ₃₁	$RE(x) \sim RE_{>0}(x)$	From SD ₂₉ and SD ₃₀ , and the axiom pertaining to RE. “If something requires something else to be, it requires this to some extent greater than zero, and vice versa.”
SD ₃₂	$\neg RE_{<\infty}(x) \sim RE_{\infty}(x)$	From SD ₂₉ and SD ₃₀ , and the axiom pertaining to RE. “If something does not totally require something else in order to exist, it requires something else in all relations, and vice versa.”
SD ₃₃	$\neg(\exists x) RE_{\infty}(x)$	From SD ₂₉ and SD ₃₁ . “There is nothing that in all relations requires something else in order to exist.”
SD ₃₄	$(\exists x) RE_0(x)$	Suggested by ID ₆ and ID ₃ , second part. From SA ₂ , SD ₃₁ , and SD ₁₁ . “There is something that in no relation whatsoever requires something else in order to exist.”
SD ₃₅	$RE_{<\infty}(x) \sim RC_{<\infty}(x)$	Suggested by SA ₁₈ . “If something does not totally require something else in order to exist, it does not in all relations require other conceptions in order to be conceived, and vice versa.”
SD ₃₆	$(x) RC_{<\infty}(x)$	From SD ₃₅ and SD ₂₉ . “All things, each taken separately, are conceived through some other things in less than all relations.”

GRADING BASIC DISTINCTIONS

SD37	-RC(x) in chapters 1–3 $\underline{\text{Def}} \text{RC}_0(x)$	“In what follows, -RC(x), as it occurs in chapters 1–3, shall mean the same as $\text{RC}_0(x)$.”
SD38	$\text{RC}_0(x) \sim \text{RE}_0(x)$	From SD37, SA18, and SD30. “If something does not at all require the conception of something else in order to be conceived, neither does it require anything else in order to exist, and vice versa.”

Carefully elaborated, these and other theorems may contribute to a highly original life and worldview (*Leben und Weltanschauung*). In contemporary jargon, such worldviews might be labeled biocentric, ecocentric, or cosmocentric: all beings have a series of common properties and urges, and there is some kind of supreme whole.

Grading Other Previously Introduced Predicates

SD39	$\text{L}_{>0}(x) \sim \text{ES}_{>0}(x)$	Suggested by SD17. “If something is free to some extent, it is in itself to some extent, and vice versa.”
SD40	$(x) \text{L}_{>0}(x)$	From SD39 and SD2. “All things are to some extent free.”
SD40a	$\text{H}(x) \supset \text{L}_{>0}(x)$	From SD40. “Every human being is to some extent free.”
SD41	$\neg(x) \text{L}_{<\infty}(x)$	From SD11 and SB19. “Not everything is less than completely free.”
SD42	$\text{L}(x)$ in chapters 2 and 3 $\underline{\text{Def}} \text{L}_{\infty}(x)$	Suggested by SD4 and SB14. “From now on $\text{L}(x)$, as it occurs in chapters 2 and 3, shall be taken to mean the same as $\text{L}_{\infty}(x)$.”

SD43	$(\exists x) L_{\infty}(x)$	From SD17, SD24, and SB16. “There is something that is completely free.”
SD43a	$(x) (y): L_{\infty}(x) \& L_{\infty}(y) \supset x = y$	From SB14, SD42, and SD11a. “There is one and only one thing that is totally free (Spinoza’s God).”
SD43b	$ES_{\infty}(a) \& CS_{\infty}(b) \& L_{\infty}(c) \supset a = b = c$	“If a thing a is totally in itself, a thing b is conceived totally through itself, and a thing c is totally free, then a , b , and c are the same thing.”
SD44	$PCNE_{<\infty}(x) \sim EA_{<\infty}(x)$	Suggested by SA3 and SB6. “If something in less than all relations can be conceived as non-existent, it is in less than all relations in something else, and vice versa.”
SD45	$ENPC_{>0}(x) \sim L_{>0}(x)$	Suggested by SD2 and SB10. “If something in at least some relations cannot be conceived except as existent, it is to that extent free, and vice versa.”
SD45a	$H(x) \supset ENPC_{>0}(x)$	From SD40a and SD45. “Every human being is such that in at least some relations he cannot be conceived except as existent.”

Power Relations

SD46	$P_{<\infty}(x) \sim PCNE(x)$	Suggested by ID1 and IP11Dem3. “If something is less than infinitely powerful, it can be conceived as nonexistent, and vice versa.”
------	-------------------------------	--

GRADING BASIC DISTINCTIONS

SD47	$P_{<\infty}(x) \sim EA_{<\infty}(x)$	From SD46 and SB6. Suggested by IP11Dem3. “If something has less than adequate power in all relations, it is (to some extent) in something else, and vice versa.”
SD48	$P_{\infty}(x) \sim ES_{\infty}(x)$	Suggested by IP11Sch. From the definition of $d(x)$ and the axiom pertaining to P and SA1. “If something has adequate power in all relations, it is (completely) in itself, and vice versa.”
SD49	$P_{\infty}(x) \sim CS_{\infty}(x)$	From SD48 and SA13. “If something has adequate power in all relations, it can be adequately conceived through itself in all relations, and vice versa.”
SD50	$P_{\infty}(x) \sim AdD(xx)$	From SD48 and SC17. “If something has adequate power in all relations, it is its own adequate cause in all relations, and vice versa.”
SD51	$P_{<\infty}(x) \sim InD(xx)$	From SD46 and SC27. “If something is less than infinitely powerful, it can only be an inadequate cause of itself.”

The power terminology may be used without grading.

SD52	$(y) P(xy) \sim ES_{\infty}(x)$	From SD48. “If something is powerful in relation to all things, then it is totally in itself, and vice versa.”
------	---------------------------------	---

SD53	$(\exists y) P(xy) \& (\exists z) \neg P(xz) \sim EA_{>0}(x)$	From SD47. “If something is powerful in relation to at least one thing, and not powerful in relation to at least one thing, then this something is to some extent in something else.”
SD54	$P_{in}(x) \sim ES_{in}(x)$	Suggested by SD47 and SD48. “An increase in power mutually implies an increase in the level of being in oneself.”
SD55	$P(xy) \sim L(xy)$	“If something is powerful in relation to something, it is free in that relation.”
SD56	$\neg(\exists x): H(x) \& ES_{\infty}(x)$	From SC44. “There is no human being that is completely in himself.”
SD57	$\neg(\exists x)(y): H(x) \& P_{\infty}(xy)$	From SD56 and SD48. “There is no human being with adequate power in every relation.”
SD58	$(x)(\exists y): H(x) \supset P_{<\infty}(xy)$	From SD46 and SC43. “Every human being lacks adequate power in at least one relation.”
SD59	$P_0(x) \sim EA_{\infty}(x)$	Suggested by IIID1 and IIID2. “To be completely powerless is to be completely in something else.”
SD60	$\neg(\exists x) P_0(x)$	From SD59 and SD10. “Nothing is utterly powerless.”
SD61	$(\exists x) P_{\infty}(x)$	From SD11 and SD48. “At least one thing is infinitely powerful.”

GRADING BASIC DISTINCTIONS

SD62	$P(xy) \sim G(xy)$	Suggested by IIID2 and IVP37Sch1. “If something has adequate power in relation to something else, it is adequately active in this relation, and vice versa.”
SD63	$AdP(xy) \sim AdD(xy)$	Suggested by IIID1, IIID2, and IVPSch1. From SD62 and SC34. “If something has full power in relation to something else, it causes this latter thing adequately, and vice versa.”
SD64	$AdP(xy) \sim AdC(xy)$	From SD62 and SC36. “If something is adequately powerful in relation to something, the latter is conceived adequately through the former, and vice versa.”
SD65	$P_{in}(x) \sim G_{in}(x)$	Suggested by IIID2 and IIID3. “An increase in level of power mutually implies an increase in activeness (level of activity).”
SD66	$P_{in}(x) \sim ES_{in}(x)$	Suggested by SD48. “An increase in level of power mutually implies an increase in level of being in itself.”
SD67	$P_{in}(x) \sim EA_{de}(x)$	Suggested by SD66. “An increase in level of power mutually implies a decrease in level of being in something else.”
SD68	$P_{in}(x) \sim L_{in}(x)$	Suggested by SD66 and SB14. “An increase in level of power implies an increase in level of freedom, and vice versa.”

SD69	$\text{InP}_{\text{in}}(x) \text{Def} (\exists y) \text{P}_{\text{in}}(xy) \\ \& (\exists z) \neg \text{P}_{\text{in}}(xz) \\ \& \neg (\exists t) \text{P}_{\text{de}}(xt)$	<p>“The symbol $\text{InP}_{\text{in}}(x)$, ‘$x$ increases its power, but only in part,’ shall stand for ‘There is at least one relation in which x increases its power, and at least one in which x does not increase its power, but there is no relation in which x decreases its power.’”</p>
SD70	$\text{InP}_{\text{de}}(x) \text{Def} (\exists y) \text{P}_{\text{de}}(xy) \\ \& (\exists z) \neg \text{P}_{\text{de}}(xz) \\ \& \neg (\exists t) \text{P}_{\text{in}}(xt)$	<p>“The symbol $\text{InP}_{\text{de}}(x)$, ‘$x$ decreases its power, but only partially,’ shall stand for ‘There is at least one relation in which x decreases its power, and at least one relation in which x does not decrease its power, but there is no relation in which x increases its power.’”</p>

Similar symbols may be introduced in relation to some previous predicates:

SD71	$\text{InES}_{\text{in}}(x) \text{Def} (\exists y) \text{ES}_{\text{in}}(xy) \& (\exists z) \neg \text{ES}_{\text{in}}(xz) \& \neg (\exists t) \text{ES}_{\text{de}}(xt)$
SD72	$\text{InG}_{\text{in}}(x) \text{Def} (\exists y) \text{G}_{\text{in}}(xy) \& (\exists z) \neg \text{G}_{\text{in}}(xz) \& \neg (\exists t) \text{G}_{\text{de}}(xt)$
SD73	$\text{InL}_{\text{in}}(x) \text{Def} (\exists y) \text{L}_{\text{in}}(xy) \& (\exists z) \neg \text{L}_{\text{in}}(xz) \& \neg (\exists t) \text{L}_{\text{de}}(xt)$

It may be argued that $\text{InP}_{\text{in}}(ab)$ as an instance of $\text{InP}_{\text{in}}(xy)$ does not make sense because the relation of a to b is *one* relation, and its power is either increased or decreased in this relation. We shall, however, sometimes suppose that a has many relations to b , and that a may be increasing by being active in some but not in all relations. The time dynamic is important in this regard.

These definitions facilitate our transition from Spinoza’s power philosophy to his philosophy of emotions. The above facilitates an understanding of how Spinoza’s philosophy of power differs from Thomas Hobbes’s; Spinoza’s philosophy of emotion does the same thing.

V

The Road to Freedom Through Active Emotion

Introduction

There are many kinds of power according to Spinoza. There are also many kinds of joy. Considering the internal relation between joy and perfection, there must also be many kinds of perfection.

Perhaps the increase of a particular power at least sometimes leaves intact or even reduces the general (total) power of an individual. The purely or unmixed active emotions, the emotions of which there cannot be too much, necessarily increase the general power of an individual. This offers us a connecting link between active emotion and previous notions. We have already introduced the notion of increasing and decreasing power. Emotion is something through which power increases or decreases. The relation is such that whenever power of some kind or other increases or decreases, there is necessarily emotion. The intimacy of the relation limits the validity of the phrase “emotion is something by *means of which* the power increases or decreases.” Whenever all-embracing general or total power increases there is unmixed active emotion, and whenever there is unmixed active emotion there is an increase in total power. We may think of dwelling in a situation we find perfect—nothing we might hope for is left out. The body and soul, the whole personality, are engaged in the situation or the process or in something that is both a situation and a process. On the other hand, total power may be left intact in the case of contrary emotions, that is, when one kind of power increases and another decreases.

An emotion may be strong or weak, persistent or short-lived. We shall suppose that an increase in total power is proportionate to the joint effect of duration and intensity of active emotion. Thus, the more intense and durable the active emotion, the greater the forward leap in power. Now, an increase in power is, according to SD63, an increase in freedom. *The road to freedom is*

therefore the road to activation of emotion. The more active, intense, and persistent the emotions, the more rapid are the transitions to higher levels of human freedom. Lack of emotion, whether active or passive, implies a standstill in the level of freedom. As we start at low levels, lack of emotion arrests development. If the Greek *ataraxia* is interpreted to be an emotionless state, Spinoza spurns *ataraxia*. He does not favor moderation of emotion if this implies an upper limit of intensity or duration. There is no limit to the intensity or duration of *amor intellectualis Dei*, one of the most prominent Spinozistic emotions. The many authors who consider Spinoza a sort of Stoic or who otherwise class him together with wise men in favor of general limitation of the intensity of affects, have been misled. It must be admitted that Spinoza often uses *passio* and *affectus* as synonyms for passive emotions, for emotions that do not go together with increase in power and freedom. His terminology must be considered to be vacillating and open to misinterpretation at this point. But this does not invalidate our conclusion. Active love and joy are emotions.

Making use of the basic equivalences, one may state a series of propositions: increased intensity of active emotion results in increased (1) freedom, (2) level of being in oneself, (3) extent to which one is an adequate cause of one's actions, and (4) understanding of oneself.

After the definition of emotion or "affect" (IIID3), Spinoza writes that when we can be an adequate cause of an affect, the affect is itself an "action" (in the wide sense used by Spinoza); if we cannot be an adequate cause, the affect is a "passion." In what follows, I shall distinguish completely active emotions from those that are not completely active. In the first case we are an adequate cause; in the latter, only an inadequate cause.

Spinoza does not believe in any free will. The will of a free man is not free. We do not need a free *will* in order to be free. It is enough that the person as a whole is free—never mind isolated faculties or components of a person such as will. The will is subordinate to the person as a whole.

Humans do not deliberately choose the road to freedom and reject the road to slavery. Such a primordial choice is not necessary because there is a tendency, a certain striving, *conatus*, inherent in all noneternal, finite—that is, limited—things and therefore in every human being.

An aspect of this general *conatus* is the so-called self-preservation or, better, self-perseveration—the striving to remain in one's own being (*in suo esse perseverare*, IIP6). It is a striving toward *consolidation of a being as far as it*

is in itself. It is a tendency to withstand threats to the level already reached of being in itself.

In addition to this, or as an aspect of it, there is a no less fundamental striving to increase the extent of being in itself. This striving increases in force proportionally to the level reached (in other words there is an exponential increase). Humans, and every other living being, have this latter striving. In humans it expresses itself as a desire for clearer and more comprehensive understanding (*intelligere*). The “law of exponential increase” is common to all, but the level at any age may differ considerably from person to person. According to part V of the *Ethics*, the deeper a person is involved in “understanding of the third kind,” the more strongly he desires to have more of it, and the more capable he is of reaching what he desires.

Evidence supporting the above general interpretation is furnished mainly by IIP6, IIP7, IIP9, IIP9Sch, VP25, and VP26. I leave it as an open question whether Spinoza would apply the term *understand* to all living beings. Perhaps *conceiving*, as a weaker and more general term, should be used in the case of nonhumans.

Our human striving toward being in ourselves is, if our basic equivalences hold, also a striving for being conceivable through ourselves, that is, completely and clearly understandable *for* and *from* ourselves. On the other hand, the striving is also one of avoiding being passive in relation to other things, or being acted upon rather than taking the initiative.

The principle of self-preservation is formulated by Spinoza in such a way that it seems that its function is merely to preserve a level of in-itself, which is already reached. The principle is used, however, in a way that implies a striving toward *increased* freedom, power, and perfection. The *conatus* is preserved, not a definite stage of development. There are various ways of reformulation that can bridge the gulf between the uninspiring status quo formulation of IIP7 and the requirement of his system as a whole. One way is to postulate that the self alluded to in IIP6 and IIP7 comprises basically a striving toward higher levels, and that therefore a preservation of the self includes the preservation of the striving toward higher levels. This preservation will then not be one of conservation of a measured level, but of the positive derivative of a function like $f(x) = x^2$.

The development of personality consists of, or at least involves, a gradual integration of imperfectly related emotions of which Spinoza recognizes more than eighty classes. To those classes of emotions correspond sets of

powers and sets of fields of action and cognition. The progress toward freedom depends on the “feedback” from different dispositions for emotion, through cognition—an emotion that represses an active emotion will itself be repressed, and emotion that enhances an active emotion will be enhanced. The “victorious” emotion will be such that it represses none of the active emotions and enhances some or all. Here we meet *hilaritas*, and taking the object-relation into the picture, the *amor intellectualis Dei*.

The above account of the consolidation of the person through increasing the level of “being in oneself” may be used to formulate a theory of personal identity that is consistent with David Hume’s discussions of absolute identity as well as other criticisms and contemporary discussions of “loss of personal identity.” The outcome of such an attempt is uncertain, but I see no genuine obstacles in spite of the not uncommon, Hegel-inspired view that Spinoza lets the individual person disappear in substance or God. If any disappearing is involved, however, it is rather the disappearance of God as a substance in the particular beings.

A remark may be relevant here concerning description and construction. Spinoza has written very little compared to the extent of the problems he covers. It is therefore natural when we ask, What has Spinoza said about this? that the answer is frequently “very little” or “nothing.” Considering also the formidable range of diversity of well-documented interpretations of his text, it is doubtful whether one can pin down his views on anything at all using words and expressions clearly understandable in this age. What we can do as philosophers, however, is to work out reconstructions, as opposed to mere “descriptions” of his views. We can work out comprehensive views that are not only inspired by Spinoza’s text but are also not clearly incompatible with the text.

Having this outlook, it is difficult to see how I could ever report as Ruth L. Saw (1969: 4) does about some of her investigations:

A long-treasured and wishfulfilling belief of mine has finally disappeared—the belief that Spinoza was promising us an account from which we might draw Peter in all his particularity as the object of our highest knowledge.

From a narrow historical point of view there is nothing definite in Spinoza’s text that militates *against* the belief that “disappeared,” nor is there anything definite to support this “disappearance” directly and clearly. A re-

construction may be worked out “in Spinoza’s spirit” that would contain theorems from which we can infer that Peter in his particularity is a proper object of the third kind of knowledge. Is this not enough?

In the following survey, I plot out an easy way to test the consequences of our interpretation of the doctrine of essential striving. Plotting out the theorems, I presuppose an interpretation of emotion and its relation to different kinds of cognition that is argued in detail in *Conation and Cognition* (Naess and Wetlesen 1967). The interpretation of IIID₃ stated in *Conation and Cognition* is the basis for the first theorem.

Survey E Using Symbols

New Symbols:

$F(x)$	x is in the state of emotion (<i>affectus</i>)
$AdF(x)$	x is in the state of active emotion
$InF(x)$	x is in the state of passive emotion; x is in a state of passion
$\dots O(x)$	x strives to increase its level of \dots
$\dots NO(x)$	x strives against an increase in its level of \dots x strives to reduce its level of \dots
$ESO(x)$	x strives to increase its level of being in itself
$EANO(x)$	x strives against an increase in its level of being in something else

Survey E

States of Emotion

SEI	$F(x) \sim P_{in}(x) \vee P_{de}(x) \vee InP_{in}(x) \vee InP_{de}(x)$	Suggested by IIID ₃ . “If x is in a state of emotion, x increases or decreases its power in all or some relations, and vice versa.”
-----	--	---

THE ROAD TO FREEDOM THROUGH ACTIVE EMOTION

From the definition of $P_{in}(x)$, it follows that we may simplify SE1:

$$SE_{1a} \quad F(x) \sim P_{in}(x) \vee P_{de}(x)$$

In other words, we shall take “state of emotion” to be a state of change in power, and we shall take a state of power change to be a state of emotion.

SE2	$\neg F(x) \sim \neg P_{in}(x) \& \neg P_{de}(x)$	From SE1. “If something is not in a state of emotion, it neither increases nor decreases, totally or partially, its power, and vice versa.”
SE3	$P_{in}(x) \supset F(x)$	Follows from SE1. “To increase one’s power implies to be in a state of emotion.” “Without emotion, there is no increase in power. Emotion is a necessary but not sufficient condition for increasing power.”
SE4	$AdF(x) \sim P_{in}(x)$	Suggested by IID3. “Being in a state of active emotion mutually implies increasing one’s power.”
SE5	$AdF(x) \supset G(x)$	From IID3. “If something is in a state of active emotion, it is active.”
SE6	$(y) AdF(xy) \sim (y) P_{in}(xy)$	From SE1 and SE4. “If something is in completely active emotion toward all things, it increases its power in all relations.”

To increase in power, $P_{in}(x)$, need not be the same as to increase in every relation, $(y) P_{in}(xy)$. If x has a small decrease in one relation and a great increase in all others, x will have an increase in total power, but not in every relation. Thus, $(y) P_{in}(xy)$ implies $P_{in}(x)$, but not vice versa.

SE 7	$F(x) \sim \text{AdF}(x) \vee \text{InF}(x)$	Suggested by IIID ₃ . “If something is in a state of emotion, it is either in a state of fully active emotion or in a state of more or less passive emotion.”
SE8	$\text{InF}(x) \sim \text{P}_{\text{de}}(x) \vee \text{InP}_{\text{de}}(x) \vee \text{InP}_{\text{in}}(x)$	From SE ₁ , SE ₄ , and SD ₇₀ . “If something is in a (more or less) passive emotional state, it is either decreasing its power, totally or partially, or only increasing it partially, and vice versa.”
SE9	$\text{InF}(xy) \sim (y) \text{P}_{\text{de}}(xy) \vee (\exists z) \text{P}_{\text{de}}(xz) \& (\exists t) \neg \text{P}_{\text{de}}(xt) \& \neg (\exists t) \text{P}_{\text{in}}(xt) \vee (\exists u) \text{P}_{\text{in}}(xu) \& (\exists v) \neg \text{P}_{\text{in}}(xv) \& \neg (\exists w) \text{P}_{\text{de}}(xw)$	“To be in a state of passive emotion is mutually equivalent to a total decrease in power, or to undergo a partial decrease and no increase, or to undergo a partial increase and no decrease in power.”
<p>If there is a partial increase of power in one relation and a partial decrease in another, the total state of emotion will be considered to be complex and to be constituted by two emotions. This is a consequence of definitions SD₆₄ through SD₆₇.</p> <p>A woman might decrease “just a little” in power in relation to her husband but increase “considerably” in relation to her children. She would still be in a state of passive emotion according to the definitions. This shows the limited value of the definitions. For the sake of simplicity, we do not take into account quantitative changes in power.</p>		
SE ₁₀	$\text{AdF}(x) \sim \text{ES}_{\text{in}}(x)$	Follows logically from SE ₄ and SD ₆₆ . “If something is in a state of active emotion, it is increasing its level of being in itself, and vice versa.”

THE ROAD TO FREEDOM THROUGH ACTIVE EMOTION

SE₁₁ $P(x) \supset \neg F(x)$ From SE₁.
 “If something is infinitely powerful, it is not in an emotional state.”

This rules out God and substance being emotional—which would have been an awkward consequence of our reconstruction!

SE₁₂ $AdF(x) \sim AdD_{in}(x)$ Follows logically from SE₁₀ and SC₁₄.
 “If something is in a state of fully active emotion, it increases totally its level of adequateness as a cause, and vice versa.”

SE₁₃ $AdF(x) \sim G_{in}(x)$ Follows logically from SE₄ and SD₅.
 “To be in a state of fully active emotion is to increase one’s general level of activity.”

SE₁₄ $AdF(x) \sim L_{in}(x)$ Follows logically from SE₁₀ and SB₁₄.
 “To be in a state of fully active emotion is to increase one’s general level of freedom.”

SE₁₅ $AdF_{in}(xy) \sim L_{in}(xy)$ From SE₁₄.
 “If one increases one’s level of active emotion in relation to something, one increases one’s level of freedom in relation to this something, and vice versa.”

SE₁₆ $L_{in}(x) \supset F(x)$ Follows from SE₃ and SD₆₈.
 “To increase one’s freedom implies to be in a state of emotion.”

Without emotion there is no increase in freedom. Emotion is a necessary but not sufficient condition for increasing freedom. The importance of this for educational institutions is formidable: Do they do their utmost to

inspire active emotions and steady increases of such emotions? Are, for instance, the ways in which mathematics and history organized conducive to elicit and maintain positive emotions?

Basic Human Striving

SE17	$(x): H(x) \supset ESO(x)$	Suggested by IIIP7Dem. “For all x it holds that if x is a human being, x strives to increase his level of being in himself.”
SE18	$(x): H(x) \supset EANO(x)$	Suggested by SE17 and SA1. “All human beings strive to decrease their level of being in something else.”
SE19	$(x): H(x) \supset -RENO(x)$	From SE17 and SA12. “All human beings strive to reduce the extent to which they require something else in order to exist.”
SE20	$(x): H(x) \supset CSO(x)$	From SE17 and SA13. “Every human being strives to conceive more through himself.”
SE21	$(x): H(x) \supset CANO(x)$	From SE17 and SA6. “All human beings strive to reduce the extent to which they are conceived through something other than themselves.”
SE22	$(x): H(x) \supset -RCO(x)$	From SE17 and SA6. “Every human strives to be such that he requires fewer things to conceive in order to conceive himself.”
SE23	$(x): H(x) \supset PCNENO(x)$	From SE18 and SB6. “All humans strive to reduce the conditions under which they can be conceived as nonexistent.”

THE ROAD TO FREEDOM THROUGH ACTIVE EMOTION

SE24	$(x): H(x) \supset LO(x)$	From SE17 and SB14. “All humans strive to be more free.”
SE25	$(x): H(x) \supset CO(x)$	From SE17 and SC15. “All humans strive to improve their understanding.”
SE26	$(x): H(x) \supset PO(x)$	From SE17 and SD48. “Every human strives to increase his power.”

All these strivings are conceptually different. The connotations of the terms differ. According to our basic interpretation of the fundamental equivalences (of the *in se* class), however, the denotations or extensions are identical. We may give general striving the name of “self-realization” (or self-preservation or self-perseveration), but this may not help our reconstruction of Spinoza’s system. Similarly, it does not help to identify general striving with *conatus*.

General Striving

Spinoza concentrates his attention on the striving of men, but acknowledges a general striving of *all* particular things. The striving for self-preservation (IIIP6, IIIP7, and so on) is the best known. For reasons given later, such striving cannot be separated from the strivings mentioned in the foregoing. We may therefore tentatively write in complete generality:

SE27	$(x) ESO(x)$	“All particular beings strive to increase their level of being in themselves.”
SE28	$(x) PO(x)$	“All particular beings strive to increase their power.”
SE29	$(x) LO(x)$	“All particular beings strive to increase their level of freedom.”

An attempt to generalize SE20, SE21, and SE25 leads to difficulties. Spinoza is generally regarded as favoring animism (of some kind), and an

extension of his notion of ‘conceiving’ to cover all particulars is not out of place. But, thus extended, it presumably would not have much in common with the notion of ‘conceiving’ as applied to humans. We leave the subject, noting an unsolved structural difficulty. In SE27 through SE29, I use the term *beings* instead of *things*, which would be the closest translation of Spinoza’s term *res*. I personally would like to restrict the use of *beings* to living beings, interpreting “living” in a more or less wide way.

VI

Joy

Under this chapter I have arranged the discussion of a fairly large number of phenomena: joy, sorrow, cheerfulness, pleasurable excitement, melancholy, pain, self-preservation, self-realization, and alienation. The title of the chapter is motivated by the unique place of various forms of joyousness in Spinoza's philosophy.

The mind undergoes considerable changes (*magnus mutationes*) according to Spinoza. It moves to a higher or lower state of perfection (IIIP₁₁Sch) and it increases or decreases in power. The changes reveal the nature of the basic affects joy and sorrow (. . . *explicant affectus laetitia et tristitia*). In the definitions IIIAffD₂ and IIIAffD₃ the term *perfectio* occurs. In this section we eliminate it in favor of *potentia*, using the equivalence of the two terms suggested at the end of IIIAffD₃E.

Introducing the term *joy* (*laetitia*) we shall use the opening sentence of IVP₄₁Dem: "Joy (IIIP₁₁ and IIIP₁₁Sch) is the emotion through which the power of the body to act, increases or is furthered." It is not *only* the body that profits through joy, which would be profoundly un-Spinozistic. According to IIIP₁₁, that which tends to increase the body's power to act tends to increase our power to cogitate (think). And in IIIP₁₁Sch, joy is defined as the passion through which the *mind* becomes more perfect.

Survey F Using Symbols

Joy

On the basis of this we introduce the following:

SFI	$\text{Lae}(x) \sim P_{\text{in}}(x)$	Suggested by IVP ₄₁ Dem and IIIP ₁₁ .
-----	---------------------------------------	--

JOY

		<p>“If there is joy there is an increase in power, and vice versa.”</p> <p>“To be in joy is to (be in affect and) increase one’s power, and vice versa.”</p>
SF1a	$Lae(x) \sim (\exists y) P_{in}(xy)$	<p>From SF1.</p> <p>“When a being is in joy, it increases in power in at least one relation, and vice versa.”</p>
SF2	$(\exists y) P_{in}(y) \supset Lae(x)$	<p>“To increase in power, in part or totally, implies to be in joy.”</p>

All increases in power are joyful. We leave it undetermined which class of x ’s this holds for. It holds at least for human beings. Considering Spinoza’s animistic tendency, the class may be rather large, covering at least living beings.

SF3	$Lae(x) \sim ES_{in}(x) \vee InES_{in}(x)$	<p>From SD61, SD67, and SF1.</p> <p>“To be in joy is to increase one’s being in oneself, partially or totally.”</p>
SF4	$Lae(x) \sim (\exists y) L_{in}(xy)$	<p>From SD63, SD67, and SF1.</p> <p>“To be in joy is to become freer, in some or all respects.”</p>
SF5	$L_{in}(x) \supset Lae(x)$	<p>“To increase in freedom implies to be joyous.”</p> <p>Joy is a necessary condition of advancement in freedom.</p>
SF5a	$(x): H(x) \supset LaeO(x)$	<p>From SE26 and SF1.</p> <p>“Every human being strives to be joyous.”</p>

The striving to be joyous is but one aspect of the universal striving (*conatus*). If I strive to realize something, A , and there is an internal relation between A and other things, B , C , and D , it may so happen that I do not

strive to get *B* or *C* or *D*. But as symbolized, I am said also to strive for *B*, *C*, and *D* if there is a mutual implication relation between all four. Spinoza's thinking at this point favors a nonintentional term, *striving*. We may consciously say to ourselves that we strive for *A* and not *B*, but if *A* and *B* are internally related, what happens is that we are urged toward both *A* and *B*. It makes no difference whether we consciously set out to seek *A* or *B*.

The matter stands differently, of course, if there is only an *external* relation between *A* and *B*. I strive for a castle (*A*), but in all probability it ruins me (*B*). I do not strive to be ruined and I hope, by miraculous luck, to avoid ruin. No incoherence is manifest here because the two states, having a castle and being ruined, are not internally connected. In the case of joy and increase in power, or joy and increase in self-causedness, the realization of the one without the others is not possible according to Spinoza, even though we might believe we can imagine them separated. The connection between joy, sorrow, and changes in power or perfection results, if our reconstructions are not wholly misleading, in a synthesis of ontological, epistemological, and psychological components in the conception of the human situation.

The foregoing reconstructions, taken as a whole, reveal the basic relations between increases in substantiality (*in se* status), understanding, and intensification of active emotion. They also reveal the optimism in Spinoza's view of the human predicament—a view that I think is essentially correct and true. Joy and integrity, not anxiety and stress, are central in his vision. Circumstances, however, may be such that a human being lives a life of next-to-utter powerlessness, filled with hatred and frustration.

Perfection

In his survey of emotions, Spinoza defines joy as “man's transition from a lower to a higher perfection.” Accordingly, we state the following mutual implication, naming perfection “Per”:

SF6	$\text{Lae}(x) \sim \text{Per}_{\text{in}}(x)$	Based on IIIAff D2. “If you are joyous you increase in perfection, and if you increase in perfection, you are joyous.”
-----	--	---

JOY

This is a rather unusual and radical view. It seems that it implies an astonishing corollary: he who thinks he increases his perfection painfully or in an indifferent mood suffers from an illusion or grave error.

The joy theorems are apt to elicit questions such as the following: How does it feel to be in a state of *laetitia*? How does it manifest itself? Is it something like a disposition rather than a “raw feeling” or a “sensation”? Perhaps one may not be clearly conscious of *laetitia*. Alternatively, one may be conscious of it only when looking backward, as when we say, “At *that* time I felt happy and was really happy, but perhaps I did not understand it.” Concentrating on questions of structure, I shall not take up these questions at any length. There is, however, no indication in the *Ethics* that Spinoza would class a raw feeling or sensation as anything but an *ens rationis*, a construct resulting from—or, rather, useful in—analysis. In this he would only continue an old tradition starting with Democritus. The large cluster of equivalences involving joy can be incorporated in a materialistic Gestalt psychology, not in a psychology of atomic association.

The internal relation of *laetitia* to *perfectio* is less astonishing when we take into consideration that *perfectio* does not express an absolute such as the English term *perfection* tends to do. The verb *perficere* means to complete, carry through, or make into a whole.

Through SF6 we may place perfection in relation to terms introduced previously:

SF7	$\text{Per}_{\text{in}}(x) \sim \text{P}_{\text{in}}(x)$	From SF1 and SF6. “To increase in perfection is to increase in power” or, more precisely, “Increase in perfection and increase in power mutually imply each other.”
SF8	$\text{Per}_{\text{in}}(x) \sim \text{G}_{\text{in}}(x)$	Suggested by VP40. “An increase in perfection implies an increase in activeness, and vice versa.” What Spinoza says is that the more perfect a thing is, the more active it is, and vice versa.

From these theorems it is clear that *perfection* is a broad term. Its increase may increase perfection only in some aspects or relations. There may be increases that do not favor long-term further increases because of the narrowness or one-sidedness of the kind of perfection. We obtain perfections pertaining to all or to only some relations or situations corresponding to the triad joy, *hilaritas*, and pleasurable excitement.

SF9	$\text{Lae}(x) \sim (y) \text{Per}_{\text{in}}(xy) \vee \text{InPer}_{\text{in}}(xy)$	From SF6 and SF7, and definitions. “To be in joy is to increase, partially or in all respects, in perfection, and vice versa.”
SF10	$(y) \text{Per}_{\text{in}}(xy) \sim (y) \text{P}_{\text{in}}(xy)$	From SF7. “To increase in perfection in all relations is to increase one’s power in all relations, and vice versa.”
SF11	$\text{InPer}_{\text{in}}(xy) \sim \text{InP}_{\text{in}}(x)$	From SF7. “Partial increase in perfection mutually implies partial increase in power.”
SF12	$(y) \text{Per}_{\text{in}}(xy) \sim (y) \text{ES}_{\text{in}}(xy)$	From SD61 and SF10. “Total increase in perfection mutually implies total increase in level of being in oneself.”
SF12a	$\text{Per}_{\text{in}}(x) \sim \text{ES}_{\text{in}}(x)$	From SF11, SF12, and SD66. “An increase in perfection mutually implies an increase in being in oneself.”
SF13	$\text{Per}(x) \sim \text{ES}(x)$	From SF10 and SF12. “The infinite level of perfection is the infinite level of being in oneself, and vice versa.” “If something has absolute perfection, it is absolutely in itself, and vice versa.”

JOY

Strictly speaking, the following postulate is here and in analogous cases presumed valid: if an increase in level of x is equivalent to an increase in level of y , then the zero and infinite levels of x are equivalent to the zero and infinite levels of y .

It turns out that the term *complete perfection* behaves as the many *in se* or substance terms of our chapters 1 and 2. Thus:

SF14	(y) Per(xy) ~ L (x)	From SF13 and SB14. “Complete perfection is complete freedom and complete freedom is complete perfection.”
------	---------------------	---

We write L (x), not L(x) as in chapters 2 and 3, following the convention stated in SD42.

SF15	-($\exists x$) Per _o (x)	From SF7, SF10, SF11, and SD60. “There is no being without some perfection.”
------	---------------------------------------	---

Every being is an expression of God and has an essence. It may be a very modest being but not wholly conceivable through something else. We have a series of “Nothing is vanishing” theorems. No thing has: zero level in itself; zero status as cause; zero level of freedom, power, perfection; and so on. From SF7, SF10, and SF11 one may infer the equivalence of power and perfection. This makes it justifiable to maintain that “everything has perfection” corresponds to “everything has power.” The formulation “everything is perfect” would be misleading!

In the introduction to part IV of the *Ethics*, Spinoza undermines the other-directedness of perfection measured by standards unrelated to the purpose of individual beings in their particular strivings. He also effectively undermines the classical and medieval notion of a *scala naturae*, a “ladder of life,” or universal hierarchy, with man at the top. Levels of perfection are measured in relation to the strivings of *each* thing; there is no general measure such that man might be termed more perfect than an amoeba or a tree. If taken seriously, this Spinozistic view has profound consequences in many fields, including pedagogics.

SF16	$(x): H(x) \supset \text{Per}(x)$	From E17. “All human beings strive to increase their level of perfection.”
------	-----------------------------------	---

Spinoza would probably be willing to extend his theorems to a very large class of beings apart from humans.

Self-Preservation

With the ten theorems on striving, SE12 through SE21, and SF16, we cover so much *conatus* that it is difficult to see in the famous “striving (endeavor) to self-preservation” much that is new. Taken in its crudest form, the endeavor to continue to live—that is, somehow to survive—is of little systematic interest. And taken to imply a resistance to change, a striving to keep on just as one always has done, is clearly un-Spinozistic. The dynamic, interactionist view of the self makes it inevitable to interpret the principle as a striving for power, activeness, and self-causingness. This is more than the minimum undertaking: to survive. In its dynamic aspect it might simply be a general term for all of the eleven strivings we have already introduced and perhaps some more. We might connect it more specifically with the striving for perfection, for wholeness, completeness, and self-madeness, as suggested by the special use of the term in the *Ethics*. Thus, we may write:

SF17	$\text{PesO}(x) \sim \text{ESO}(x)$	“To strive for self-preservation mutually implies to strive for higher levels of being in oneself.”
------	-------------------------------------	---

The equivalences of ES, CS, and the other in-itself predicates result in corresponding theorems, for instance:

SF18	$\text{PesO}(x) \sim \text{LO}(x)$	From SF17 and SB14. “To strive for self-preservation mutually implies to strive for higher levels of freedom.”
------	------------------------------------	---

JOY

SF19	$\text{PesO}(x) \sim \text{PO}(x)$	Suggested by SD51. “To strive for self-preservation mutually implies to strive for an increase in power.”
SF20	$\text{Pes}_{\text{in}}(x) \sim \text{P}_{\text{in}}(x)$	Suggested by SF19. “Increase in self-preservation mutually implies an increase in power.”
SF21	$\text{Pes}_{\text{in}}(x) \sim \text{Per}_{\text{in}}(x)$	From SF20 and SF7. “Increase in self-preservation mutually implies an increase in perfection.”
SF22	$\text{Pes}_{\text{in}}(x) \sim \text{Lae}(x)$	From SF21 and SF6. “Increase in self-preservation mutually implies a state of joy.”
SF23	$\neg(\exists x) \text{Pes}_0(x)$	From SF21 and SF15. “There is nothing that has zero level of self-preservation.” “Everything preserves itself to some degree.”

The principle of self-preservation as exemplified and as defined by philosophers and biologists since the Stoics has a main component of defense against attack. It covers behavior and structures adapted to maintaining an equilibrium under threats from the environment. The organisms have mechanisms to counteract disturbances. Conceived in this way, the principle has acquired renewed importance through the ecology movement.

In Spinoza’s *Ethics*, the term is not defined in this way, but from the contexts we can infer what he considers to be an increase or decrease in the level of self-preservation. Even if he sometimes writes things that suggest that self-preservation is an *aim* that uses power increases and increases in freedom as *means*, there is no indication how this comes to be.

A term that is somewhat more capable of carrying the burden Spinoza places on *self-preservation* is *self-realization*. The self “is to be realized.” If the

term *self* refers to something capable of development to an expansion, self-realization is more than preservation and conservation.

It involves change from “within” by interaction with environment. The term suits Spinoza’s dynamism better than *self-preservation*. Its history is very long, going back to early Greek and Indian philosophy. Its latest bloom in the Indian tradition is Gandhi’s metaphysical notion of realizing the self, truth, and God. God is, in this metaphysics, *ātman*, not a transcendental entity. “God is not outside this earthly case of ours” (*Harijan* 13.6.1936; quoted in Prabhu and Rao 1967: 54). *Ātman* and the Self with capital *S* enjoy a kind of double manifestation, both as a universal Self and as a component (sometimes “witness” or “voice”) in individual selves.¹ It is therefore not far-fetched to link Spinoza and Gandhi at this point.

In conclusion, I propose that the predicate “increased (level of) self-preservation” is understood in the sense of “increased level of self-realization,” taking “self-realization” to be a process whereby the self or ego expands and gains in power. This process is here not conceived as something different from increasing one’s level of being in oneself. Thus, we introduce a predicate “level of self-realization” (*Sre*) and assert:

SF24	$Sre_{in}(x) \text{ ekv } ES_{in}(x)$	“An increase in self-realization is extensionally equivalent to an increase in being in oneself.”
------	---------------------------------------	---

Through this theorem, self-realization is connected with previous notions. Thus, we obtain:

SF25	$Sre_{in}(x) \sim Pes_{in}(x)$	Suggested by SF24 and SF17. “To increase in self-realization mutually implies to increase in self-preservation.”
SF26	$AdSre(x) \sim AdPes(x)$ $\sim ES(x)$	From SF25 and SF24. “To completely realize oneself, to completely preserve oneself and to be completely in oneself, mutually imply each other.”

JOY

To the opposite process of self-realization we give—not quite arbitrarily—the name “alienation.” An increase in alienation, of *in alio esse*, would then correspond to an increase in “being in something else”:

SF27 $\text{Alienation}_{\text{in}}(x) \text{ ekv } \text{EA}_{\text{in}}(x)$

But here the temptation to introduce additional terms should be curbed: *alienation* may be dropped from our structure since it points to only one of many interpretations of a heavily misused term.

Cheerfulness (Hilaritas)

[T]he emotions by which we are agitated daily are mostly related to some part of the body which is more strongly affected than others: this is why emotions mostly have an excess, and in such a way hold down the mind that it can only think of one subject and nothing else. . . . (IVP44Sch)

If strong, an emotion may impede the development of many parts of the mind and body. This is the case when it is concentrated in only one or a few parts.

Joy either affects all parts of mind and body equally, increasing the total power, or unequally, increasing the power of all parts, but unevenly. At least when intense, the unevenness directly impedes the development of the neglected parts. There may in that case be no increase in total power, understanding, or perfection.

Joy (*laetitia*) is accordingly of two kinds. Here we shall deal with the uniformly homogeneous joy affecting all parts of the person. Spinoza calls it *hilaritas*. We shall use the term *cheerfulness*.

SF28	$\text{Hil}(x) \sim (y) \text{P}_{\text{in}}(xy)$	“If somebody is in a state of (pervasive) cheerfulness then he is increasing his power in all relations, and vice versa.”
------	---	---

SF28 is suggested by IIP11Sch, IVP42, IVP42Dem, and IVP44Sch. The term *pervasive* is inserted because the cheerfulness must somehow permeate the whole person and all avenues of interaction with the world and oneself.

Hilaritas cannot exist when one is blocking the awareness of unpleasant, undigested difficulties. The state presumes the absence of repression in a psychoanalytical sense. Therefore, it is perhaps to be considered a “theoretical maximum concept” like that of an “ideal gas” or “*perpetuum mobile*,” but scarcely an *ens rationis*. It is not a mere construction used in thinking. While occurrences of *hilaritas* can be rare (*concupitur facilius, quam observatur*), Spinoza does not discount them. It is compatible with what is said in the parentheses to hold that most people often experience *hilaritas*. Obviously, to *observe* others’ or our own *hilaritas* is not so easy. One would have to make some assumptions, whereas the observation of someone jumping over a hedge can be made rather directly.

Increase in power is equivalent to increase in the other properties of the *in se* class. Using SF21, we may therefore write:

SF29	$Hil(x) \sim AdES_{in}(x)$	From SF28 and SD51a. “A state of (pervasive) cheerfulness mutually implies a state in which we increase our level of being in ourselves.”
SF30	$Hil(x) \sim CS_{in}(x)$	From SF29 and SA13. “A state of (pervasive) cheerfulness mutually implies a state of general increase of understandability of oneself through oneself.”
SF31	$Hil(x) \sim AdL_{in}(x)$	From SF30 and SB16. “A state of (pervasive) cheerfulness implies a state of increasing freedom in all relations, and vice versa.”

The cheerful person increases his level of activeness and the degree to which he causes his own reactions and states of mind:

SF32	$Hil(x) \sim AdD_{in}(xx)$	From SF31 and SC22. “A state of (pervasive) cheerfulness is one of increasing self-causation, and vice versa.”
------	----------------------------	---

JOY

SF ₃₃	$\text{Hil}(x) \sim \text{AdG}_{\text{in}}(x)$	From SF ₃₂ and SC ₃₇ . “A state of (pervasive) cheerfulness implies an increasing level of activeness, and vice versa.”
SF ₃₄	$(y) \text{Per}_{\text{in}}(xy) \sim \text{Hil}(x)$	From SF ₁₂ and SF ₂₉ . “A pervasive increase in perfection mutually implies a state of cheerfulness.”
SF ₃₅	$(y) \text{Pes}_{\text{in}}(xy) \sim \text{Hil}(x)$	From SF ₃₄ and SF ₂₁ . “A pervasive increase in self-preservation mutually implies a state of cheerfulness.”

Pleasurable Excitement (Titillatio)

A joy may correspond to a universal increase in power and perfection, or a partial increase in power and perfection with no part decreasing, or a partial increase combined with a partial decrease. In the last case we have a species of mixed feeling, which we shall leave out here. In the second case, we have *titillatio* “pleasurable excitement.” Thus, we introduce a new predicate, Tit, and state:

SF ₃₆	$\text{Tit}(x) \sim (\exists y) \text{P}_{\text{in}}(xy) \& (\exists z) \neg \text{P}_{\text{in}}(xz) \& \neg (\exists t) \text{P}_{\text{de}}(xt)$	Suggested by IVP ₄₃ Dem. “If somebody is in a state of pleasurable excitement, he increases in power in at least one, but not all, relations, and decreases in none, and vice versa.”
SF ₃₇	$\text{Tit}(x) \sim \text{InP}_{\text{in}}(x)$	From SF ₃₆ and SD ₆₅ . “To be in pleasurable excitement mutually implies to increase partially in power.”
SF ₃₈	$\text{Tit}(x) \sim \text{InES}_{\text{in}}(x)$	From SF ₃₆ , SD ₆₁ , and SA ₁₃ . “To be in pleasurable excitement

		mutually implies to increase, but only partially, one's level of being understandable by oneself."
SF39	$\text{Tit}(x) \sim \text{InL}_{\text{in}}(x)$	From SF38 and SB16. "To be in a state of pleasurable excitement mutually implies a partial increase in freedom."

These theorems give too bright a picture of *titillatio*. According to IVP43Dem, an intense *titillatio* may completely block any major increase in freedom and hold its level back at a very low state. Considering the vast possibilities for human freedom, one can imagine how increasing *titillatio* might involve a decrease in freedom. These quantitative and complex considerations do not invalidate the above theorems, but instead highlight their limited value.

Sorrow, Melancholy, and Pain

Spinoza's theorems on *laetitia*, *hilaritas*, and *titillatio* make it obvious that there are no words in English that convey the differences. The same holds for the corresponding triplet *tristitia*, *melancholia*, and *dolor*. One should therefore primarily note the conceptual bonds, the structure, and not take the translations seriously. To find suitable (complex) designations in English constitutes a task requiring extensive semantical studies.

Sorrow (*tristitia*), the negative affect corresponding to the positive joy; *melancholia*, corresponding to cheerfulness (*hilaritas*); and pain (*dolor*), corresponding to pleasurable excitement, will be introduced in an analogous way.

SF40	$\text{Tri}(x) \sim \text{P}_{\text{de}}(x)$	From IIIP59Dem and IIIP11. "Sorrow is a state of decreasing power, and the state of decreasing power is also a state of sorrow." "Sorrow mutually implies reduc- tion of power."
------	--	---

JOY

SF41	$\text{Tri}(x) \sim (\exists y) P_{de}(xy)$	From SF40. “When sorrowful, a being decreases in power in at least one respect.”
SF42	$\text{Tri}(x) \sim (y) ES_{de}(xy)$ $\vee (\exists y) ES_{de}(xy)$ $\& (\exists z) -ES_{de}(xz)$	From SD61, SD67, and SF40. “To have sorrow mutually implies a loss in level, partial or total, of being in oneself.”
SF43	$\text{Tri}(x) \sim (y) L_{de}(xy)$ $\vee (\exists y) L_{de}(xy)$ $\& (\exists z) -L_{de}(xz)$	From SD63, SF67, and SF40. “To have sorrow mutually implies a loss of freedom, partial or total.”
SF44	$(x): H(x) \supset \text{TriNO}(x)$	Suggested by SE21 and SF40. “All humans strive to avoid sorrow.”
SF45	$\text{Tri}(x) \sim (y) \text{Per}_{de}(xy)$ $\vee (\exists y) \text{Per}_{de}(xy)$ $\& (\exists z) -\text{Per}_{de}(xz)$	Suggested by SF7 and SF40. “To have sorrow mutually implies a loss of perfection, partial or pervasive.”
SF46	$\text{Tri}(x) \sim (y) \text{Pes}_{de}(xy)$ $\vee (\exists y) \text{Pes}_{de}(xy)$ $\& (\exists z) -\text{Pes}_{de}(xz)$	Suggested by SF21 and SF45. “To have sorrow mutually implies a lowering of the level of self-preservation, partial or pervasive.”

From the above, it is seen that the predicate *tristitia* (sorrow) behaves exactly like *laetitia*—only, with negative implications. Mixed states of emotion are such that components of both joy and sorrow are present.

SF47	$\text{Mix}(x) \supset (\exists y) \text{Lae}(xy)$ $\& (\exists z) \text{Tri}(xz)$	“If a being is in a state of mixed emotion, both joy and sorrow are present to some degree.”
------	---	--

The joy may move practically all parts of the person, the sorrow only a very limited set. To get into such a state may represent an improvement in overall power, an increase in self-preservation, and so forth. We perform, to take an example, a joyful task, but it may involve physical pain.

There is, however, a state with no such consoling features: melancholy, the polar opposite of cheerfulness.

SF48	$\text{Mel}(x) \sim (y) P_{\text{de}}(xy)$	Suggested by IIP11Sch. “Melancholy is the state in which we decrease power in every relation, and vice versa.”
SF49	$\text{Mel}(x) \sim (y) G_{\text{de}}(xy)$	Suggested by SD60 and SF48. “A state of melancholy is one of total decrease in activeness, and vice versa.”
SF50	$\text{Mel}(x) \sim (y) CS_{\text{de}}(xy)$	From SF49 and SC38b. “Melancholy is such that there is a pervasive decrease in understanding of things through oneself, and vice versa.”
SF51	$\text{Mel}(x) \sim (y) \text{Pes}_{\text{de}}(xy)$	Suggested by SF48 and SF20. “A state of melancholy mutually implies a reduction of self-preservation in all relations.”

Last of all, the negative effect, “pain” (*dolor*), corresponds to the positive effect “pleasurable excitement.”

SF52	$\text{Dol}(x) \sim (\exists y) P_{\text{de}}(xy)$ $\& (\exists z) \neg P_{\text{de}}(xz)$ $\& \neg (\exists t) P_{\text{in}}(xt)$	Suggested by IVP43Dem. “To be in pain is to be in a state such that there is a decrease of power in at least one relation, a lack of decrease in power in at least one relation, and no relation in which power is increased.”
------	--	---

Pain experienced during pleasurable undertakings does not fall under SF41, because of the partial joy present. More importantly, discomfort and conditions that, during emotionally neutral or negative time intervals,

JOY

should be experienced as painful, are normally not thus experienced if the integrated undertaking as a totality is one of joy. If a person is about to carry the assembly toward his own conclusion on an important matter, he is unlikely to experience as painful the polluted air, hard chair, slight toothache, or moderate thirst. If there is a clearly dominant joyful relation, circumstances that are mostly experienced as heavily painful, distressing, or frustrating will not appear as such. All this seems implied in Spinoza's teaching, as conceived in the foregoing—with the addition of the superior efficacy of joy insofar as it increases the power of the person. Sorrow tends to have more sorrow as a feedback; joy has joy as feedback. This is part of the background for Spinoza's claim that *love* is more potent than *bate*.

SF53	$\text{Dol}(x) \sim \text{InP}_{\text{de}}(x)$	From SF52 and SD65. "To be in pain mutually implies to decrease partially in power."
------	--	--

The letters "In" here, as shorthand for "inadequate," may mislead. *Partial* is the term we need to symbolize. (But "P" is already used for "power"!) The term *partial* suits both positively and negatively loaded predicates, *inadequate* only negative ones. In Spinoza's terminology, *partial* has a strong position because of his affinity to mechanistic or materialistic views. Inadequate conceptions are partial conceptions (never quite false!). In the expression "inadequate idea," however, it may be doubted whether *partial* is a good substitute. The inadequate idea is an unclear, vague, or loose one. The Cartesian conception of clarity and distinctness does not lend itself to the part/whole terminology.

There is also, however, important evidence here in favor of the possibility of an analysis of *inadequate* in terms of partiality (cf. pp. 32–33). The expression "clear and distinct" (*clare et distincte*) is indirectly connected by Spinoza in IIP30Sch with his part/whole terminology. There it is said that we do not obtain adequate conceptions of things when we take them as isolated. The conceptions are then confused and fragmentary (*confusa et mutilata cognitio*). But if we take notice of many things together (*res plures simul contemplatur*) with their likenesses and differences, we conceive things clearly and distinctly (*clare et distincte*). Spinoza is here able to explain inadequateness in terms of lack of clearness and distinctness and explain this lack in terms of isolation of one thing from others. That is, he shows the possi-

bility of defining inadequateness of conceptions, and therefore ideas, in terms of partiality. Clearness and distinctness will then be a property of a conception of a “whole” of interacting or interdependent parts.

“How large are these wholes?” one may ask. Ultimately, all of nature is a whole. A gradation of wholes like a gradation of *gestalts* seems warranted; if not, Spinoza would have to assert that man never has adequate conceptions because he can never “contemplate” nature as an (absolutely complete) whole.

SF54	$\text{Dol}(x) \sim \text{InCS}_{\text{de}}(x)$	From SF52, SD61, and SA13. “To be in pain mutually implies to decrease partially the level of understanding oneself through oneself.”
SF55	$\text{Dol}(x) \sim \text{InL}_{\text{de}}(x)$	From SF52 and SB16. “To be in pain is to undergo a partial loss of freedom, and vice versa.”

Pain may, under certain circumstances, be a good, and pleasure an evil, according to Spinoza. If the pleasure affects too narrow a range of “parts” too intensely, the adverse effects on other parts increase (geometrically?). This means that there is a “maximum field” for any pleasure. By an appropriate function this can, of course, also be put into symbols. For our present purposes, however, this would be pedantic, bordering even on the ridiculous.

In regard to pain, it may have a beneficial function in that in a more comprehensively conceived situation it represents an increase in power. Just as a partial joy (a pleasurable excitement) may indirectly be an obstacle to increased freedom, pain may be a positive stimulant. In short, joy is as such “good” and sorrow is as such “bad,” but under certain circumstances sorrow may help, that is, be “good,” and joy may be “bad.” This leads us to a consideration of the predicates good and bad.

VII

Good and Bad and Usefulness

The use of the terms *bonum* and *malum* in the *Ethics* suggests several, rather different, concepts. An adequate analysis would have to take into account more than two hundred occurrences with the possibility of widely different interpretations, all of them based on solid textual considerations.¹ Here we shall concentrate on an important subclass of the occurrences, in which “good” does not appear to mean something different from “useful,” when taken to include noninstrumental usefulness. That is, when asked to answer the question What is *x* useful for?, we can answer, “It is in itself useful; *x* is useful for *x*.” Thus employed, *both* intrinsic and extrinsic values may be called useful. An example of this is (IVP18Sch): “Secondly it follows that virtue is to be sought for its own sake, and that there is nothing more excellent or more useful for us. . . .”

Let us take as a point of departure something said in IVP18Sch:

Since Reason does not demand anything contrary to Nature, it demands that everyone love himself, look for what is useful, what really is useful, to himself, and that he strive to obtain all that really leads man to greater perfection. . . .

This occurrence—and many others—suggests that we may express one of the predicates intended by the designation “useful” as follows: *x* is useful if and only if it leads to increased perfection. At the same place in the *Ethics*, and clearer in IVP20Dem, the intimate relation between the useful and preservation of one’s being is expressed. Accordingly, we thus introduce usefulness:

SG1 $\text{Uti}(xy) \sim \text{D}(x(\text{Per}_{\text{in}}(yz)))$ “That something, *x*, is useful to *y*, mutually implies that it causes *y* to increase in perfection in some relations.”

The introduction of the term *cause* is problematic. The useful is primarily useful as a means, an instrument, a favorable condition for something else. Its role as cause scarcely extends much further. Or does it?

Spinoza makes a broader and more noble use of the term *useful* than we do in everyday life: friends are *most* useful. According to IVP18Sch, the useful “leads” man to higher degrees of perfection. Man is *led* by the useful. If Spinoza had developed a notion, “instrumental,” that clearly distinguished itself from the many notions of cause, we would introduce “useful” in terms of “instrumental.” But he does not. According to our plan, we introduce “good” by taking it to be synonymous with “useful” (in the selected sense):

SG2	$\text{Bon}(xyz) \text{ Def } \text{Uti}(xyz)$	“ x is good for y in relation to z ” shall mean the same as “ x is useful for y in relation to z .”
-----	--	---

From this and previous theorems we now infer some new equivalences of interest.

SG3	$(z) \text{ Uti}(xyz)$ $\sim (z) \text{ D}(x(\text{P}_{\text{in}}(yz)))$	From SF12 and SG1. “That something is entirely useful for someone mutually implies that it causes an increase in power in all relations.”
SG4	$(z) \text{ Bon}(xyz)$ $\sim (z) \text{ D}(x(\text{P}_{\text{in}}(yz)))$	From SG2 and SG3. “That something is entirely good for someone mutually implies that it causes an increase in power in all relations.”
SG5	$\text{Bon}(xy)$ $\sim \text{D}(x(\text{P}_{\text{in}}(y)))$	From IVP8Dem, and also from SG4. “That something is good for someone implies that it increases his power, and vice versa.”

Spinoza does not often talk about the disuseful or harmful. We introduce *malum* (bad) by its direct connection to decrease of power:

SG6	$\text{Mal}(xy) \sim \text{D}(x(\text{P}_{\text{de}}(y)))$	From IVP8Dem. “That something is bad for someone implies that it decreases his power, and vice versa.”
SG7	$\text{Bon}(xy) \sim \text{D}(x(\text{Pes}_{\text{in}}(y)))$	From IVP8Dem, and also from SG5 and SF20. “That something is good for someone mutually implies that it increases his level of self-preservation.”
SG8	$(z) \text{Uti}(xyz)$ $\sim (z) \text{D}(x(\text{Pes}_{\text{in}}(yz)))$	From SF21 and SG1. “Something is entirely useful if and only if it increases the level of self-preservation in all relations.”
SG9	$(\exists z) \text{Bon}(xyz)$ $\sim (\exists z) \text{D}(x(\text{Pes}_{\text{in}}(yz)))$	From SG8 and SG2, and also from IVP8Dem. “Something is good if and only if it increases the level of self-preservation in some relations.”
SG10	$(z) \text{Bon}(xyz)$ $\sim (z) \text{D}(x(\text{ES}_{\text{in}}(yz)))$	From SE10 and SG11. “If something is entirely good, it causes a pervasive increase in the level of being in oneself, and vice versa.”
SG11	$(z) \text{Bon}(xyz)$ $\sim (z) \text{D}(x(\text{AdF}(yz)))$	From SG4 and SE4. “If something is entirely good for someone, it causes him to have a purely active emotion.”
SG12	$(z) \text{Bon}(xyz)$ $\sim (z) \text{D}(x(\text{AdD}_{\text{in}}(yz)))$	From SE12 and SG11. “If x is entirely good for y , it causes y to increase its level of adequateness as a cause in all relations.”

GOOD AND BAD AND USEFULNESS

SG13	$(z) \text{Bon}(xyz)$ $\sim (z) \text{D}(x(\text{L}_{\text{in}}(yz)))$	From SE14 and SG11. “If x is entirely good for y , it causes y to increase its freedom in every relation.”
SG14	$(z) \text{Bon}(xyz)$ $\supset \text{D}(x(\text{Hil}(yz)))$	From SF31 and SG13. “If x is entirely good for y , it causes y to be cheerful.”

The foregoing theorems place “totally” or “entirely” and “useful” or “good” among the totally positive predicates. Symmetry requires the introduction of partial goodness and utility, $\text{InBon}(x)$ and $\text{InUti}(x)$, and of two sets of negative predicates, $\text{Mal}(x)$, $\text{InMal}(x)$, $\text{Inu}(x)$, and $\text{InInu}(x)$, where “Inu” represents inadequate utility. It is easily seen that we get a series of theorems corresponding to other sets of “partiality” or inadequacy theorems.

Since the useful or good is said to cause something, it is also endowed with activeness, freedom, and the other predicates we primarily—but not exclusively—attach to human beings. Thus, according to our present stipulation, we must accept $(\exists z) \text{Uti}(xyz) \supset (\exists t) \text{D}(xt)$, from which follows, $\text{L}_{>0}(x)$, $\text{ES}_{>0}(x)$, $\text{CS}_{>0}(x)$, and so on. These consequences are not serious, since we have already accepted that all particular things, as something through which God acts and as something that expresses God, have at least some rudimentary causal weight and therefore also some freedom. But what about the implications $(z) \text{Uti}(xyz) \supset (t) \text{D}(xt)$ and $(z) \text{Bon}(xyz) \supset (t) \text{D}(xt)$? Does the universally useful and good cause all things?

First, it must be noted that the implicate scarcely follows from the implications. We lack the necessary stipulations concerning the ranges of x , y , z , and t . But suppose the implication is made valid. It would raise x to the level of God: the eminently good and the eminently useful is God. Noting the role of perfection, we would have to say that if something is God, it causes gain in the perfection of all things. And if something causes perfection in all things, it is God.

Instead of accepting some or all of these consequences, we may modify or give up SG1, or accept it but make suitable stipulations concerning the ranges of x , y , z , and t . Spinoza’s text may help us make a wise decision, but he does not impose any definite one.

SG15	$Bon(xy) \sim D(x(Lae(y)))$	From IVP48Dem, and also from SG5 and SF1. “If something is good for someone, it causes him joy, and vice versa.”
SG16	$Mal(xy) \sim D(x(Tri(y)))$	From IVP48Dem, and also from SG6 and SF40. “If something is bad for someone, it causes him sorrow, and vice versa.”

Spinoza classifies sorrow (*tristitia*) itself as a bad thing (*malum*) in IVP50Dem. Is this in accordance with the introduced notion, or does it exemplify a different notion? Through sorrow we make a transition to a lower level of perfection or power, says Spinoza. But he also says that sorrow *is* the transition. Sorrow scarcely causes the transition and therefore scarcely causes sorrow. My tentative answer is that when Spinoza calls sorrow bad, he uses the term in a way that I have not yet accounted for.

VIII

Virtue and Reason

Virtue

In IVD8, and many other places, Spinoza says that by “virtue and power” he understands “the same.” This formulation is too simple to convey his thought, but it will do no harm to use it as a bridge between the new notion and our old ones:

SH1	$\text{Vir}(x) \text{ ekv } P(x)$	From IVD8. “Virtue is power, and power is virtue.”
-----	-----------------------------------	---

The simple formulation above does not cover IVD8 in its totality, but is followed by a *hoc est*, a “that is,” introducing a considerably more complex formulation. This and IVP₂₃Dem suggest:

SH2	$\text{Vir}(xy) \sim \text{CS}(xy)$	“A person acts virtuously (<i>ex virtute agit</i>) in relation to something, if this something can be understood through himself, and vice versa.”
SH3	$\text{Vir}_{\text{in}}(x) \sim P_{\text{in}}(x)$	From SH1. “Increase in action according to virtuous action implies increase in power, and vice versa.”
SH4	$(y) \text{Vir}(xy) \sim (y) P(xy)$	From SH3. “To act virtuously in all relations mutually implies to act powerfully in all relations.”

VIRTUE AND REASON

SH ₅	$\text{Vir}_{\text{in}}(x) \sim \text{L}_{\text{in}}(x)$	From SH ₃ and SD ₅₁ . “Increase in virtuous action implies an increase in freedom, and vice versa.”
SH ₆	$\text{Vir}_{\text{in}}(x) \sim \text{CS}_{\text{in}}(x)$	From SH ₂ . “Increase in virtuous action implies an increase in level of understandability through one-self, and vice versa.”
SH ₇	$\text{Vir}_{\text{in}}(x) \sim \text{Pes}_{\text{in}}(x)$	From SH ₃ and SF ₂₀ . “An increase in level of virtue implies an increase in level of self-preservation, and vice versa.”
SH ₈	$\neg(\exists x) \text{Vir}_o(x)$	From SH ₅ and SD ₄₀ . “No being is without some virtue.”
SH ₉	$(\exists x) \text{Vir}(x)$	From SH ₅ , SB ₁₄ , and SD ₁₁ . “There is at least one thing that is absolutely virtuous.”
SH ₁₀	$(x)(y): \text{Vir}(x) \& \text{Vir}(y) \supset x = y$	From SH ₅ , SB ₁₄ , and SD _{11a} . “There is one and only one thing that is absolutely virtuous.”

This implies that if two or more entities are absolutely virtuous, they are identical.

The last two theorems unambiguously point toward God or Substance or Nature as something absolutely virtuous. This might not be Spinoza’s intention. But it is very difficult for him to avoid the implications. The clearly stated, intimate relations between virtue, freedom, and power are difficult to dissolve without undermining a score of theorems in the *Ethics*.

In the present reconstruction, the notion of God is a special kind of maximum concept, and the above theorems are perfectly digestible within the system.

SH11	$\text{Vir}_{\text{in}}(x) \supset F(x)$	From SE16 and SH5. “To increase one’s level of virtue implies being in a state of emotion, and when one increases in virtue, one is in a state of emotion.”
SH12	$\text{Vir}_{\text{in}}(x) \sim \text{Lae}(x)$	From SH3 and SH11. “The one who increases in virtue is in a state of joy, and the one who is in a state of joy increases in virtue.”
SH13	$(y) \text{Vir}_{\text{in}}(xy) \sim \text{Hil}(x)$	From SH3 and SF28. “The one who increases in virtue in all relations is in a state of cheerfulness, and vice versa.”
SH14	$(x): H(x) \supset \text{VirO}(x)$	From SH3 and SE21. “Man strives to raise his level of virtue.”
SH15	$\text{Bon}(xy) \sim D(x(\text{Vir}_{\text{in}}(y)))$	From SH3 and SG5. “That something is good for someone implies that it increases his level of virtue.”
SH16	$\text{Uti}(xy) \sim D(x(\text{Vir}_{\text{in}}(y)))$	From SG2 and SH15. “That something is useful for someone mutually implies that it increases his level of virtue.”

Reason

According to IVP56Dem, “to act out of virtue [*ex virtute*] is nothing else than to act out of reason [*ex ductu rationis*].” In IVP24 and IVP36Dem the same point is made.

SH17	$\text{Vir}(x) \text{ ekv } \text{Rat}(x)$	From IVP56Dem. “To act virtuously is to act according to reason.”
------	--	--

VIRTUE AND REASON

We shall refrain from stating the sixteen theorems analogous to SH1 through SH16 that follow from SH17, by inserting “Rat” for “Vir.” We shall, however, make explicit the relation of rationality and emotion.

SH18	$\text{Rat}_{\text{in}}(x) \supset F(x)$	From SH11 and SH17. “When increasing one’s level of rationality, one is in a state of emotion.”
SH19	$\text{Rat}_{\text{de}}(x) \supset F(x)$	Suggested by SH17, SH1, and SF40. “When decreasing one’s level of rationality, one is in a state of emotion.”
SH20	$(y) \text{Rat}_{\text{in}}(xy) \sim \text{Hil}(x)$	From SH17 and SH13. “A pervasive increase in rationality mutually implies a state of cheerfulness.”
SH21	$\neg \text{Hil}(x) \supset \neg (y) \text{Rat}(xy)$ & $\neg (y) \text{Vir}(xy)$	Suggested by SH17 and SH20. “Absence of cheerfulness implies a complete absence of virtue and reasonableness.” “If someone acts without cheerfulness, he or she acts without complete virtue or reasonableness.”
SH22	$(y) \text{Rat}_{\text{de}}(xy) \sim \text{Mel}(x)$	Suggested by SH17, SH1, and SF48. “If a person decreases pervasively in rationality, he is in a state of melancholy, and vice versa.”

Accordingly, in every case of melancholy—as conceived by Spinoza—there is a pervasive decrease in rationality.

Spinoza stresses the close connection between “acting from reason” and freedom when he states, “The free man, that is, the man who lives only ac-

cording to what reason dictates . . .” (IVP57Dem) and “I say that he who is free only follows reason” (IVP58Dem).

SH23	$(x)(y) \text{ Rat}(xy)$ $\text{ekv } (y) \text{ L}(xy)$	Suggested by IVP58Dem. See also IVP67Dem and IVP4Sch. “The completely rational is the completely free.”
SH24	$\text{Rat}_{\text{in}}(x) \sim \text{L}_{\text{in}}(x)$	From SH23. “Increase in rationality and increase in freedom mutually imply each other.”

In IVP73, Spinoza makes a well-known statement (already quoted): “The rational man [*homo qui ratione ducitur*] is more free in society . . . than alone.” From this it may be inferred that a person can maintain a stable, high level of rationality while alone: only in such a case would Spinoza call him a rational person. But it may also be inferred that stability in level of rationality is consistent with variations in degrees of freedom: if a rational man can leave the state of loneliness and enter a society, he would change his level of freedom. The last conclusion is clearly against our theorem SH24. Various moves are open. One is to give up the mutual implications between freedom and rationality. This, however, conflicts with clear confirmations in the text of the implications (cf. IVP54Sch, IVP57Dem, IVP58Dem, IVP67Dem, IVP68Dem, and IVP72Dem). If we nevertheless gave up these implications, a number of others might also be considered highly vulnerable, and the hypothesis of structural simplicity would have to be reconsidered.

A second approach is more reasonable: to declare that what is said in IVP73 does not amount to more than the statement that “The man who has reached a high level of rationality will find the environment of a state better suited for maintaining the level and improving on it, than any other environment.” This tack amounts to accepting the hypothesis that the use of “more free” (*magis liber*) is somewhat loose in IVP73.

A third approach, closely related to the second, is simply to declare that the occurrence of “more free” in IVP73 does not belong to the occur-

VIRTUE AND REASON

rences of “free” that our reconstruction pretends to cover. This might seem self-defeating to some, but an interpretation that could be *shown* to be in harmony with *every* occurrence of the principal terms of the *Ethics* is out of reach. The best way to obtain a realistic view of what we can hope to attain is to go through lists of occurrences of such terms. Consistency is only reached through more or less free reconstructions and the acceptance of a series of more or less historically unsupportable semantical hypotheses. Authors who seem to hold implicitly that the set of their interpretative hypotheses is perfectly consistent with every occurrence of every term involved, may perhaps not have carried out any analysis at all. Would such work perhaps make Spinoza’s appreciators less enthusiastic about trying to apply his work or less sure the text can be of any help in life? The immense complications may repel them.

SH25	Rat(xy) ~ Vir(xy) ~ Pes(xy)	From IVP24. “To behave rationally, to act virtuously, and to preserve one’s being in relation to something, all mutually imply each other.”
------	--------------------------------	--

In IVP24, Spinoza equates “to act *absolutely* out of virtue” (*ex virtute absolute agere*) with the other two nonabsolute predicates, but such a dissymmetry would disturb the whole structure. The restless identification of the three on the level of connotation (*haec tria idem significant*) in the same proposition (IVP24) creates difficulties, to say the least.

The above comments are, I hope, well suited to make one realize that reconstructions cannot and should not follow *every* move in the thoughts and expressions of a great philosophic author.

IX

Self-Satisfaction

In what follows, a very tentative extension of the foregoing reconstruction is suggested. Love and self-satisfaction (*acquiescentia in se ipso*) are defined by Spinoza in relation to the “contemplation” of objects. He notes the causes of these emotions: “Love is joy accompanied with the idea of the external cause of the joy” (IIIAffD6); “Self-satisfaction is joy originating from man’s contemplation of himself and his power of action [*agendi potentia*]” (IIIAffD25). When trying to understand the latter notion, it is also profitable to inspect what Spinoza has to say about the opposite, humility (IIIAffD26, IVP53, and IVP53Dem).

Man’s power expresses itself in actions or activeness, in part unobservable by everyday means. What we may have as *latent* power does not concern us here. Accordingly, I take the emotion of self-satisfaction to refer to certain acts of reflection, that is, acts through which our activeness is “contemplated.”

I shall not assume that such meta-acts automatically follow acts as their shadows. Nor do I assume the possibility of an act being carried out without accompaniment of any act of reflection. Two quotations may be relevant here:

When the mind conceives itself and its power of activeness, it rejoices, and does so the more, the more distinctly it imagines itself and its power of acting (IIIP53).

He who has a true idea at the same time knows that he has a true idea, and cannot doubt the truth of the thing (IIP43).

Spinoza seems to assert that when we adequately cause something, that is, when we adequately conceive something, we also automatically and adequately conceive that we adequately conceive. We conceive our own activeness, our own essence, and we are gladdened. This joy, however, is itself an

SELF-SATISFACTION

act (cf. SE5) and presumably perceived adequately. If we do not choose our words with care, we may end up postulating an endless series of acts that, unavoidably, are instigated by a single process of adequate causation or conception.

Introducing a predicate “ x is in the state of self-satisfaction through contemplation of y ,” we ask the following question: has this variable, y , already appeared in the previous reconstruction?

When a person causes something adequately, he manifests active power (*agendi potentia*); we may therefore write:

SJ1	$\begin{aligned} &\text{AdD}(xy) \\ &\quad \& \text{Refl}(x, \text{AdD}(xy)) \\ &\quad \supset \text{Acq}(x) \end{aligned}$	<p>“If a person causes something adequately and contemplates (reflects on) this, he is in a state of self-satisfaction.”</p>
-----	---	--

This notation does not do justice to all the complexities of the idea of self-satisfaction but suffices to bring some essential features into our reconstruction. According to previous theorems, adequate causation is linked to other *in se* predicates. Are we willing to accept the implications?

SJ2	$\begin{aligned} &\text{AdC}(xy) \\ &\quad \& \text{Refl}(x, \text{AdC}(xy)) \\ &\quad \supset \text{Acq}(x) \end{aligned}$	<p>From SJ1 and SC3. “If a person conceives something adequately, and contemplates this, he is in a state of self-satisfaction.”</p>
SJ3	$\begin{aligned} &\text{AdG}(xy) \\ &\quad \& \text{Refl}(x, \text{AdG}(xy)) \\ &\quad \supset \text{Acq}(x) \end{aligned}$	<p>From SJ1 and SC37. “If a person is fully active in relation to something and contemplates this, he is in a state of self-satisfaction.”</p>
SJ4	$\begin{aligned} &\text{AdP}(xy) \\ &\quad \& \text{Refl}(x, \text{AdP}(xy)) \\ &\quad \supset \text{Acq}(x) \end{aligned}$	<p>From SJ1 and SD58. “If someone has full power in relation to something and contemplates this, he is in a state of self-satisfaction.”</p>

This theorem may well suggest itself from the very definition of self-satisfaction, IIIAffD25.

SJ5	$\begin{aligned} &\text{AdL}(xy) \\ &\quad \& \text{Refl}(x, \text{AdL}(xy)) \\ &\quad \supset \text{Acq}(x) \end{aligned}$	<p>Suggested by SJ4 and SD51.</p> <p>“If a person is fully free in relation to something and he contemplates this, he is in a state of self-satisfaction.”</p>
-----	---	--

All these theorems suggest, but do not presuppose, that self-satisfaction requires “optimum processes,” such as adequate causation, complete freedom, and so on. But Spinoza distinguishes higher and lower satisfaction (VP27) and also works in other ways with self-satisfaction as a graded predicate.

According to the definition of self-satisfaction, it is a kind of joy.

SJ6	$\text{Acq}(x) \supset \text{Lae}(x)$	<p>From IIIAffD26.</p> <p>“When one is in a state of self-satisfaction, one is in a state of joy.”</p>
SJ7	$\begin{aligned} &\text{AdD}(xy) \\ &\quad \& \text{Refl}(x, \text{AdD}(xy)) \\ &\quad \supset \text{P}_{\text{in}}(x) \end{aligned}$	<p>From SJ1, SJ6, and SF1.</p> <p>“When one is an adequate cause of something and reflects on this, one increases in power.”</p>
SJ8	$\begin{aligned} &\text{AdP}(xy) \\ &\quad \& \text{Refl}(x, \text{AdP}(xy)) \\ &\quad \supset \text{P}_{\text{in}}(x) \end{aligned}$	<p>“When one is adequately powerful in relation to something and reflects on this, one increases in power.”</p>

The increase in power is an increase in power in relation to something, z , and presumably in an adequate way:

SJ9	$\begin{aligned} &\text{AdP}(xy) \\ &\quad \& \text{Refl}(x, \text{AdP}(xy)) \\ &\quad \supset (\exists z) \text{AdP}(xz) \\ &\quad \& z \neq y \end{aligned}$	<p>“When one is adequately powerful in relation to something and reflects on this, one is adequately powerful in something else also.”</p>
-----	--	--

SELF-SATISFACTION

On contemplating the new power relation, we obtain joy and a new adequate power relation. There is, in principle, no limit here, but the exercise of higher-order reflection is presumably a very special case relating “only to a part of our body (and mind).” *Hilaritas* cannot be reached this way! By avoiding the theory of automatic reflection, we avoid the infinite series of meta-reflection. We may jump off when it suits us. The way to *hilaritas* is not blocked.

Mutual implications permit us to add a series of similar “chain reactions.” For instance:

SJ10	$\begin{aligned} &\text{AdL}(xy) \\ &\& \text{Refl}(x, \text{AdL}(xy)) \\ &\supset \text{AdL}(xz) \& z \neq y \end{aligned}$	<p>Suggested by SJ9 and SD63.</p> <p>“When adequately free in relation to something and reflecting on this, one is also adequately free in relation to something else.”</p>
------	--	---

This symbolization does not express that the new freedom is created through the old.

SJ11	$\begin{aligned} &\text{AdRat}(xy) \\ &\& \text{Refl}(x, \text{AdRat}(xy)) \\ &\supset \text{Acq}(x) \end{aligned}$	<p>Suggested by SJ10 and SH23.</p> <p>“Contemplation of an adequately rational relation implies self-satisfaction.”</p>
SJ12	$\begin{aligned} &\text{AdVir}(xy) \\ &\& \text{Refl}(x, \text{AdVir}(xy)) \\ &\supset \text{Acq}(x) \end{aligned}$	<p>From SJ11 and SH17.</p> <p>“Contemplation of an adequately virtuous relation implies self-satisfaction.”</p>

With this terminates our systematic introduction of terms equivalent to the basic *in se* and *in alio* terms. Of *in se* terms not introduced, several should be mentioned:

“x is God”

“x is substance”

“x partakes of God’s nature”

“the essence of x involves the existence of x ”

“it belongs to the nature of x to exist”

“the definition of x implies the existence of x ”

“ x acts according to the laws of x ’s nature”

“ x is determined to exist and operate through x ”

In relation to all of these terms, sets of theorems may be asserted that are analogous to the sets formulated in the foregoing exposition. Some of them are firmly based on the text of the *Ethics*; others are inferred on the basis of the requirements of consistency. As an example, one may note that in IVP24Dem, to act virtuously is identified with action according to (or “out of,” *ex*) the laws of one’s own nature. By means of analogous references, the above terms or predicates can be integrated into our reconstruction.

A note on the ranges of predicates: At the end of our structural study of selected predicates, one might think we are in a better position to find out about their ranges—the class of values, their extension, the things of which the predicates can meaningfully be predicated. We have touched on the subject several times. The texts are silent, however, or are, at best, vague. Some of the terms studied, for instance, *self-preservation* and *power*, are applied not only to humans, but also to animals and perhaps all living things. The equivalences, if used without restriction, imply that all the terms can be applied meaningfully to all living beings. Spinoza is remarkably different from the Cartesians in applying the predicates: he tends toward very wide applications, whereas the Cartesians are influenced by the spirit/body dualism and view human beings and God as sole possessors of spirit.

We cannot doubt that animals have feelings (*sentire*), Spinoza says in IIIP57Sch. They have emotions (*affectus*). But their joys (*gaudium*) are different from those of human beings. Their drives are different, and the differences are greater than those between humans. Here Spinoza not only talks about mammalia, but also about fish and insects.

The passive emotions are confused ideas (*idea confusa*) and the active emotions are clear ones (IIIAffGenD). Thus animals, having emotions, also have ideas and minds. When active, they not only have ideas, but consis-

SELF-SATISFACTION

tency demands that they also have ideas about ideas (cf. IIP58 and the theorems on self-satisfaction). There are, in short, no theorems in the *Ethics* to stop us in our attribution of all the introduced predicates to living beings “down” to insects or even further. The only qualification has to do with differences within each genus of entities. Living beings very different from us have correspondingly different joys, drives, and so on. How they are, Spinoza does not pretend to know. But, for his system, I think we must recognize that a very wide range of application of the predicates is essential.

All particular things are expressions of God; through all of them God acts. There is no hierarchy. There is no purpose, no final causes such that one can say that the “lower” exist for the sake of the higher. Every living being may, if the requisite power is there, use any other. There is an ontological democracy or equalitarianism—which, incidentally, greatly offended his contemporaries, but of which *ecology* makes us more tolerant today.

However generous in his attributions, the range of a predicate such as “virtuous” or “in harmony with what is rational” cannot be applied meaningfully to the beings of the mineral kingdom. I find it unfruitful, however, to draw a line at any particular place. With this rather negative conclusion, we shall leave the tantalizing question of the range of Spinozistic predicates. Perhaps we might permit Wordsworth to have the last word:

“To every Form of being is assigned,”
Thus calmly spake the venerable Sage,
“An *active* Principle: —howe’er removed
From sense and observation, it subsists
In all things, in all natures; in the stars. . . .”

From William Wordsworth, *The Excursion*, Book IX.

Series Editor's Introduction

Arne Naess — A Wandering Wonderer: Bringing the Search for Wisdom Back to Life

[The pre-Socratics'] attitude, in the main, was genuinely scientific whenever it did not merely embody the prejudices of their age. But it was not *only* scientific; it was imaginative and vigorous and filled with the delight of adventure. They were interested in everything—meteors and eclipses, fishes and whirlwinds, religion and morality; with a penetrating intellect they combined the zest of children.

From this point onwards, there are first certain seeds of decay, in spite of previously unmatched achievement, and then a gradual decadence. What is amiss, even in the best philosophy after Democritus, is an undue emphasis on man as compared with the universe.

Bertrand Russell, *History of Western Philosophy*

When the full scope of Arne Naess's philosophical contribution is examined carefully and placed in context, it will very likely be viewed as one of the twentieth century's most significant and enduring.¹ Naess has made bold and innovative contributions to conventional academic philosophy and social research, particularly in the areas of behaviorist epistemology, empirical semantics and communication theory, scepticism, scientific and cultural pluralism, Gandhi and Spinoza scholarship, normative systems theory (as a general approach for exploring premise-conclusion relations), and the very idea and relevance of total systems (total views in Naess's *lingua*). Perhaps even more significant—although one should not view it as distinct or decoupled—has been his commitment to reconnect philosophy to life experience. This effort is similar to Bertrand Russell's in that it has been particularly pronounced in later life. Naess, however, carries this com-

SERIES EDITOR'S INTRODUCTION

mitment to expand philosophy's sphere of concern to life in general and the Earth. Essential to this endeavor, is the mature Naess's radical initiative to reconceptualize reason expansively, to integrate reason with emotions and feelings *in practice*. In some cases this includes using mythopoetics to make a case or communicate a point.² What makes Naess so special is that even while paddling against the current, he exhibits tremendous optimism and openness, joy, and a disarming, infectious playfulness.

Naess strives to *live his philosophy*. For more than thirty years, he has sought to reshape the philosophical debate by drawing from and building on his previous work to outline a nondualistic, nonanthropocentric philosophy of life that affirms the ultimate unity and interdependence of all living beings, while maintaining their individuality. His philosophy celebrates the Earth's richness and diversity—both cultural and biological. That said, one of the main purposes of the *Selected Works of Arne Naess* (SWAN), however, is to provide you, the reader, with the resources to make your own informed judgment regarding the significance of Naess's philosophical legacy.

At age ninety-two, Arne Naess has lived a long life filled with wonder. In his words, he has “seen life”—traveling the world, spending significant periods of time on every continent. He has experienced the world somatically and intellectually in concert as one mind-body—as a being—and seen more than most of us can imagine.

When Naess was born, Archduke Francis Ferdinand was alive, automobiles were in their infancy, and most homes did not have running water. Home refrigerators had just begun to be produced. Television and computers were only imagined. Only a few years before, after being contemplated for millennia, the first controlled and sustained powered flight took place, ushering in a period of ever-accelerating transfer of materials and information, but not necessarily a commensurate increase in knowledge or wisdom.

Consider that Naess has lived through two world wars (and too many “limited” conflicts to count), the rise and fall of the Soviet Union and East Germany, the “liberation” of India and Pakistan, the onset of climate change, and the hastening of “global terrorism.” He has been the beneficiary of tremendous medical advances and unprecedented economic growth, and he has seen the ravages caused by escalating consumption, globalization, and disparities in both income distribution and access to resources. He is part and product of humanity's largest growth spurt. And he has witnessed the most significant loss of cultural diversity and the onset of

what may become the planet's greatest extinction crisis—but is surely the greatest extinction crisis ever caused by one of Earth's own species. Naess has also seen and, at times, participated in the many hopeful responses to these ills—the peace, social justice, and ecology movements; nonviolent actions to support antiglobalization efforts and protest dam building; voluntary simplicity; conservation biology; wildlands philanthropy; bio-regionalism; green business and architecture; ecological design, economics, engineering, and restoration; and sustainable agriculture, forestry, and fisheries management.

Everyone is influenced by the times and events of his or her day. The “prejudices of our age” filter into our lives and work more or less consciously and actively, but at a minimum they enter passively. What is the mature Naess's approach to philosophy, how is it a uniquely self-aware and responsive product of his day, and why should it be seen as monumental?

Naess likes to see himself as a “philosopher of life.” The thought of simply being an academic philosopher—living a life of the mind—makes him restless and uneasy. For Naess, “wonder” is both the point of departure for philosophy and the focus of the enterprise. He is the philosophical equivalent of a hunter-gatherer using his wits and intuition to seek out food (for thought) in a fecund landscape. As they were for the ancient Greeks, science and philosophy are inextricably intertwined for Naess. Science, as the application of reason through empirical investigation, cannot be separated from rational reflection on the nature of reason, and vice versa. For the mature Naess, though, philosophy and science are also distinct. Philosophy is the unique realm in which we take up the deepest, most profound, and most fundamental problems. From Naess's vantage, which defines philosophy openly and discursively, the questions that have fascinated and plagued people for millennia have not changed much and they are not likely to change significantly in the future.

Naess's view of philosophy includes the traditional epistemological question “What can we know?” and the ontological question “What main kinds of things are there?” But it also includes “How do we measure?” and “How do we know?” as well as “What is the relationship between the knower and the known?”³ These are questions that are likely to vary with cultural and social circumstances, but this does not, for Naess, imply cultural relativism. By its nature, this view of philosophy runs counter to the dream of the logical empiricists; it cannot be restricted to investigations of

SERIES EDITOR'S INTRODUCTION

“fact” or “logic.” It is imbued with fundamental valuations. Being a philosopher, for Naess, is thus a deeply personal and intimate matter that requires us to engage all of our powers and experience. It should also include questions such as “What are your aims in life?” and “What’s driving you?” as well as encourage a practice of deep and open argumentation by asking repeatedly, “Why do you hold that *p*?” in order to unearth underlying premises and hypotheses. For Naess, all these questions have an empirical component. He sees it as a duty for a philosopher to extend research into the creation and use of empirical methods to address these aspects, unless these questions can be adequately addressed by an existing empirical science, in which case it is fine for a philosopher to perform research here, but it no longer constitutes a *duty*.

In Naess’s view, philosophy is ultimately concerned with how *we*, through our experiences, perceive the world, the world’s relation to ourselves, and the basic features of the condition of people. It is the realm in which we pose sophisticated questions to address perennial problems, probe them from different angles (in Naess’s case, from as many angles as possible), and test and apply the insights to real life—to what we do and decide every day. Its purpose is not to arrive at definitive answers. The purpose of philosophy, rather, is to help us understand what *we* believe in from our innermost perspective, expand this perspective continually, and facilitate communication—so that we might contribute toward improving the state of affairs of the world.

While initially attracted to Bergson’s *les données immédiates de la conscience* (the immediate data of consciousness), Naess grew disenchanted when he recognized that one becomes lodged in an endless circular loop and never exits consciousness. Naess clearly believes that the unexamined life is not worth living (his life is a testament to Socrates’ edict), but he appreciates that disembodied, introspective examination comes at great peril. A mind-centered focus on “examination”—where subjects exist separately from objects, theory is isolated from praxis, and knowledge is decoupled from wisdom—very quickly degenerates into meaninglessness. Worse yet, separating people from and raising people above nature and the coevolutionary process that created us—and provides for our sustenance—can be inimical to life and the evolutionary process.

Nature, that which is, the reality of the pre-Socratics, is Naess’s philosophical palette, not the “world” of his own consciousness as has become

the norm with so many contemporary philosophers since Descartes. Popper and others posit the existence of three worlds that correspond to the development of our commonsense view of reality. World I is the physical world, the "external world," the world of our sensory impressions. World II is the world of all conscious experience, the psychological world of the "immediately given," which incorporates our feelings and intentions. World III emphasizes the logical content of reality. Naess finds these multiple views of reality unconvincing and potentially dangerous. With a worldview inspired by Spinoza's *Ethics*, he is fundamentally opposed to the notion of multiple worlds.

Naess's mature philosophical approach and contributions are shaped by full engagement with a relational reality, in which no firm subject/object, substance/property, universal/particular, fact/value dualities exist. John Muir's famous, deceptively simple aphorism sets the stage: "When we try to pick out anything by itself, we find it hitched to everything else in the universe." Reality as we experience it, according to Naess, is a dynamic, multilayered manifold of hierarchically related *gestalts*—of which we are always a part. It is the opposite of atomism. Contrary to the dominant, Western way of viewing reality, there are no extrinsically connected discrete objects or "things in themselves" in the sense of Kant's *Ding an sich*. With Naess's "gestalt ontology," there is no dualistic "I" standing outside of reality looking in. Living beings, individuals in the sense of Spinoza's modes, are spatiotemporal manifestations of "one substance," nature or reality. As Naess points out in *Freedom, Emotion, and Self-Subsistence* (SWAN VI), Spinoza's medieval terminology of substance, mode, attribute, God, and Nature is dispensable. In addition, Naess goes on to characterize "living beings" broadly to include individual organisms as well as ecosystems, rivers, mountains, and possibly Earth (Gaia).

Naess's view of reality calls for a gestalt shift. His gestalt ontology does not stop with gestalt psychology's simple notion of holism, where the whole is more than the sum of the parts. It goes on to add that the internally related subordinate *gestalts* are themselves more than mere parts. There are no parts as parts or wholes as wholes; higher-order wholes are not reducible to lower-order wholes. The concrete contents of reality have gestalt character. For Naess, we experience reality spontaneously and our experience of the world is made up of *gestalts*. "[This] is the world we experience. Nothing is more real."⁴ People create abstract structures to reflect

SERIES EDITOR'S INTRODUCTION

on or analyze spontaneous experiences and their structure; they are the interrelations between spontaneous experiences. Mind and body are mental contrivances and conveniences—abstract structures in Naess's parlance—for helping us to describe, model, or understand certain states of affairs. They are not the contents of reality. Only individual occurrences of spontaneous experience make up the concrete contents of reality.

What are the consequences of Naess's "ontological realism" as expressed in the form of gestalt ontology? First, living organisms have different levels of access to reality, based on their capacities, experiences, and backgrounds. This implication of "reality is one" plays a central role in the mature Naess's approach to philosophy of science. One of his main thrusts is to undermine the claim that the exact physical sciences show all that is, that they have a privileged view of reality. In his view, science creates extremely abstract structures of what is real, but those structures do not actually *describe* any of reality's concrete contents (descriptions are themselves normative). Jakob von Uexküll, the famous ethologist of the early twentieth century, whom Naess read closely in his youth, helps clarify this notion. "As the spider spins its threads, every subject spins his relations to certain characteristics of the things around him, and weaves them into a firm web which carries his existence."⁵

Different people experience reality differently, yet we often, incorrectly, speak of *different realities* as if they existed. By the same token, identical accounts of reality in no way imply verification of that view by correspondence; from Naess's perspective, such accounts by themselves are merely a sign of cultural poverty. "God" could have created the Earth and life 6,000 years ago, but the evidence to support this case is thin and the evidence to support evolution is stronger, in part because biological science and paleontology generally employ a greater level of depth of intention and thus aspire to maintain higher standards for the evaluation of evidence. Radical pluralism and scientific possibilism do not imply scientific or ethical relativism.

There are at least four other key implications of Naess's gestalt ontology. First, the existence of one, interdependent reality tends to curb solipsism. Second, the world we live in spontaneously can no longer be characterized as merely subjective. Expressions such as "the social construction of nature" become oxymoronic. Third, individual organisms exist as knots in a biospherical web or net. Reality is not anthropocentric; it is not particular

SERIES EDITOR'S INTRODUCTION

to humans. Fourth, humanity can no longer justifiably be seen in opposition to a separate object—nature. This insight tends to temper any “natural” tendencies toward anthropocentrism. As with Leopold’s Land Ethic, people become plain members and citizens of the biotic community, albeit ones with unique powers and proclivities and thus special responsibilities. We are all individual beings, yet we vary in the extent to which we are integrated into the whole.

Humans are massively altering the gestalt character of reality, diminishing it, making it less complex. We do this, Naess argues, without necessarily recognizing we are doing it or the extent to which we are doing it. Thus, we are unable to evaluate the tradeoffs of making such decisions. Naess argues that we generally act simply according to how we “see” reality, but there are aspects of reality that may not be available to us. These aspects are no less there because they are currently unavailable to us, yet they can be destroyed very easily. Sometimes we also confuse our abstract structures of reality (models, data, concepts, etc.) with the contents of reality and vastly underestimate the complexity of internal relations between gestalts, leading ourselves to believe, incorrectly, that higher-order wholes can be reduced to lower-order wholes. It is Naess’s hope that by embracing gestalt ontology, we are encouraged to cultivate our opportunities and faculties for experiencing reality more fully—for experiencing more complex, higher-order gestalts. It is also his hope that we will openly and more carefully consider, in advance, how a proposed research program, action, or decision might affect other peoples’ (or other life-forms’) opportunities for rich spontaneous experiences (consider, for example, the possible impacts of ostensibly beneficial research on nuclear fission or molecular biology). In the end, however, we should remember Naess’s own caution—his description of gestalt ontology is itself an abstract structure. As Naess says, “For me reality has always been something slippery to handle. I seem to grasp it firmly, but like an eel, or even a small lively trout in shallow water, firmness of grasp does not guarantee against escape.”⁶ But does reality really have gestalt character?

Truth—as in *the* truth—is not a defensible notion for Naess. For too many academic philosophers, wonder has been extinguished and replaced by a belief that definitive answers have been found, that the original, initially vexing questions can be laid to rest. Naess is under no such illusion. He views humans as essentially fallible and he sees this domain of fallibility

SERIES EDITOR'S INTRODUCTION

as extending to mathematics and formal logic. This may be why he so freely returns to previously explored material (sometimes just after writing it) and looks at it afresh, with new and frequently competing and even conflicting insights. For Naess, truth is something we seek continually without expecting or believing that it can be found. He seeks peace of mind (*ataraxia*) by suspending judgment (*epoché*). While necessity requires him to take firm positions in life, he often resists taking such positions in his written philosophy. Having reached a general state of mental suspense (*isothenia*), he prefers, as a mature sceptic, anticipating his own tendency to come up with counterarguments and counter-counterarguments, to suggest alternative paths, inspire new ways of looking at things, and foster informed, open-minded debate. This *zetetic* inclination, although nascent in many of his earlier works, was made explicit and became a central theme in his philosophical writings in the 1960s.

For Naess, passivity has no place in philosophy or life. In his famous debate with Sir Alfred Ayer, Naess defines Spinoza's *amor intellectualis* as a "kind of loving attitude towards what you have insight into, while considering it in an extremely wide perspective."⁷ For the mature Naess, *amor intellectualis* involves using his technical and intellectual training to articulate, in direct and forceful ways, his attitudes and evaluations on matters of practical consequence. Like Spinoza and Gandhi, Naess is concerned with human salvation in this world, but Naess, with his concept of "wide-identification," expands this concern to both humankind's relationship to life in general and the self-realization of all life-forms for their own sake. Whether it be understanding how lay people conceptualize truth or experts characterize democracy; considering how our approach to science not only shapes how we do science, but the nature of scientific outcomes too; using philosophy to improve practical communication; facilitating thoughtful debate on the potential dangers of Norway joining the European Union; or discussing the ethics of climbing, the meanings of sustainable development, or distinctions between different approaches for addressing the ecological crisis, Naess seamlessly connects philosophical questioning to activeness in relation to the questions.

Naess's philosophical career can be seen, in one sense, as an attempt to bridge C. P. Snow's two cultures. Believing that the central questions of philosophy are here to stay, he has developed his philosophy over seventy years in part through his effort to relate these questions to the issues of his

rapidly changing, trying, and tumultuous era. Naess's lifelong commitment to integrate interests in nature, science, and logic is evidenced by the mature Naess's championing of philosophical approaches in which both metaphysics and science contribute to all-embracing systems of thought. This approach is particularly prominent in Naess's development of normative systems theory, a strategy for promoting systematic reflection on premises and conclusions. Recognizing that all philosophical questioning must stop somewhere, Naess calls the essential intuitions that serve as bedrock assumptions for our total views, ultimate norms or ultimate premises. Further, recognizing that our philosophical conclusions as well as our lifestyles and everyday actions often appear inconsistent with these ultimate premises, Naess has developed a strategy for using premise-conclusion strings to help identify potential norm conflicts as well as to help assess whether potential agreements and disagreements are real or pseudo. Use of this technique figures prominently in Naess's approach for improving communication, in his approach for exploring both the philosophical basis for Gandhi's *satyāgraha* (active nonviolent resistance) and the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," as well as in his own Ecosophy T.⁸

With regard to total views—broad philosophical systems like Spinoza's, which attempt to communicate our deepest insights and communicate views of life—Naess argues that although the existence of complete, explicit total views is absurd, it is equally absurd to presume to criticize a total view without adopting one (at least implicitly). After relinquishing the possibility of creating a consistent empirical theory of knowledge, Naess came to believe that any theory of knowledge presupposes all major philosophical disciplines, at least on the metalevel. One cannot have a theory of knowledge without presuming a particular reality, at least implicitly, and this necessitates having an ontology, metaphysics, ethics, and so on. This has practical consequences too. We never simply act solely as a philosophy professor who specializes in logic or ethics; we are always, at least partly, mother, daughter, lover, scientist, . . . , and philosopher. If we accept the premise "For every decision we, explicitly or implicitly, take all things into consideration," then the notion of total views or total normative systems can be seen as very "useful fictions," which, if articulated, might help us to improve decision making.

Naess is careful to point out that he sees his own total view and others

SERIES EDITOR'S INTRODUCTION

as fragmentary and constantly evolving—ever “on the way.” Moreover, even if we could have a completely formed and integrated total view, we could not count on being able to articulate it. There will always be a tension between the Spinozistic goal of clarity and the pragmatic reality that in this world we can never wait until all the facts are in. None of these issues, however, justifies abdicating our responsibility to try to articulate our own total views. The mature Naess is a radical pluralist. He believes in defending coherent systems, without claiming that their relation to reality is definitive. While he is committed to the importance of models and systems, he is opposed to the idea that there could or should be a definite worldview. Naess’s hope is that there will be no definite scientific worldview in the future.

No Western philosopher since Descartes—except perhaps Spinoza, who has also been a primary inspiration for Naess—has had the potential to help us drastically reshape our relationship to each other and life in general: not by spelling out *a* clear and coherent total system—to be taken as *the* truth—but by challenging us to articulate our fragmentary total views and connect the abstract problems of philosophy to issues of contemporary social and political conflict. In Naess’s view, “[t]he full meaning of a theory can only reveal itself in practice, and practice is blind without theory.”⁹ To be a philosopher of life, one must embrace both theory and practice and engage them in dance.

In Norway, Arne Naess is regarded as a national treasure, a seeker and a seer, a “minor prophet,” in his own words. His radical pluralism and endorsement of diversity are demonstrated by his complex character. He has a proclivity for being aloof and charming, somber and joyful, accountable and carefree, arrogant and modest, slippery and precise. In a world of contradictions—breathtaking beauty *and* ineffable squalor and suffering—Naess is no exception. He is an antiguru guru. He strives for high levels of consistency and integration in his philosophy but accepts that in his personal life he cannot live up to his philosophical systems’ requirements. He strives for definiteness of intention, yet he appreciates vagueness and eschews dogma, refusing to be pinned down to a particular viewpoint or placed in a particular philosophical camp. This stance is further supported by his sometimes maddening tendency to revise, revise, and re-revise. As a consequence, one cannot go to any of his books or articles and find the “definitive” Arne Naess. He is a

troublemaker too, but the kind of troublemaker people want to have around because he challenges orthodoxies with an elfin irreverence. Naess stands out because his frequently outlandish and controversial views are felt deeply, reasoned carefully, and conveyed playfully.

Naess has had a profound influence on Norwegian academic life and the society as a whole. From 1939 to 1954 he was Norway's only professor of philosophy. He was chiefly responsible for organizing courses for the *examen philosophicum*, introductory examinations in logic, methodology, and history of philosophy that an entire generation of undergraduates (roughly 100,000 people) were required to take, regardless of their disciplinary focus. His unique paradigm of inquiry—emphasizing open-mindedness, empirical analysis, pluralism, a thorough grounding in philosophy and the history of ideas, and a vital concern for contemporary problems—is credited with shaping the intellectual fabric of postwar Norway. At a press conference for Naess's eightieth birthday, the Norwegian Minister of Education testified to the significance of the Norwegian version of Naess's *Communication and Argument*, one of the primary texts for the *examen philosophicum*. "We have all read it. We *still* cheat in argumentation, but now with feelings of guilt."¹⁰

Naess is also credited with rekindling the study of philosophy in Norway and with forming the Oslo school of philosophy. The section on Scandinavian philosophy in *The Encyclopedia of Philosophy* elaborates:¹¹

The philosophical milieu in Norway today [circa 1967] is determined by an internationally known and original philosopher. . . . Arne Naess . . . is the originator of a radical type of empirical semantics and the leader of the so-called Oslo group. . . . The empirical methods applied by the Oslo group employ carefully worked-out questionnaires. By the help of such questionnaires and by teamwork, philosophers of the Oslo group have carried out investigations of such expressions as "truth," "democracy," and "private enterprise." . . . If it is correct that Norwegian philosophy has had a dead period,¹² it is equally correct to assert that, primarily because of Arne Naess, Norwegian philosophy is now in the middle of a period of life and growth.

When asked to comment on this passage, Naess was emphatic about inserting an addendum to the last sentence.¹³ He was proud to convey that contemporary Norwegian philosophers pursue a wide variety of directions and employ a diversity of approaches, many independent of Naess's own line. This point is borne out by the more than forty-four permanent teaching positions currently at the University of Oslo's Institute of Philosophy

SERIES EDITOR'S INTRODUCTION

and the broad spectrum of approaches these philosophers pursue, from the analytic tradition to phenomenology and from existentialism to hermeneutics. As one of Naess's successors, Alastair Hannay, in his section on Norwegian philosophy in the *Oxford Companion to Philosophy*, has commented, "Norway enjoys a varied and vigorous philosophical life. . . . Philosophy's place in Norwegian academic life, as in the society at large, is due in large measure to Naess."¹⁴

The reach of Naess's contributions to philosophy and social research extends well beyond Norway. Significant international recognition has also come his way for these contributions. He has received the Peer Gynt Prize awarded by the Norwegian Parliament (2004), the Nature and Environment Prize from the Nordic Council (2002), the Nordic Prize from the Swedish Academy (1996), the Mahatma Gandhi Prize for Non-violent Peace (1994), and the Sonning Prize for contributions to European culture—Denmark's version of the Nobel Prize (1977). He has even been honored by five festschrifts, one each for the occasions of his seventieth, eightieth, and eighty-second birthdays and two for his eighty-fifth birthday.¹⁵ He is the founding editor of the influential journal, *Inquiry*, created to promote collaboration between philosophers and social scientists. He is also a renowned mountaineer and climber, an occasional nonviolent political activist, and father of the deep ecology movement. His social concern, sense of wonder, and trickster nature have all contributed to his success at numerous academic posts around the world—preferably near mountains or deserts—from Berkeley to Jerusalem and Helsinki to Hangzhou. He is, to this day, still a frequent international speaker.

Even with this high level of accomplishment, the significance of his work as a whole—as a gestalt—has yet to receive broad-scale appreciation outside of Scandinavia. There are many explanations for this situation.

The overarching reason has likely been the general inaccessibility of his oeuvre. This inaccessibility has many facets. Naess has been incredibly prolific, producing over four hundred publications, more than thirty of which are books. These publications span topics from argumentation theory to zeteticism, with adventures along the way at such seemingly incongruous destinations as climbing ethics, cultural anthropology, and deep ecology. His range of topics—in abundance, breadth, and depth—is trying, at best, for our increasingly compartmentalized and specialized academic communities.

In addition, the bulk of his most significant works have been out of

SERIES EDITOR'S INTRODUCTION

print for quite some time. Many of the earlier editions of the books were edited poorly and documented sparsely. A significant portion of his important articles and book chapters appears in obscure or difficult-to-find books and journals, and much of his work has remained unpublished (at least two hundred papers and several book-length manuscripts). Naess's main works appear in three primary languages, German, Norwegian, and English, although he has also written in Danish, Swedish, and French. Finally, Naess's prose can be dense and opaque, if not downright confusing. Although this trait is by no means unusual for a philosopher, when blended with Naess's appreciation for vagueness and ambiguity, his aversion to authoritative stances, and his tendency to revisit topics by reconsidering earlier viewpoints, the already high entrance fee can become prohibitive.

The boundless range of Naess's interests and the general inaccessibility of his entire oeuvre have led some scholars to view him rather pejoratively as a dilettante. Some of these critics view him as flitting from one area of interest to another, not mining any to its logical conclusion; some see him as throwing away a great talent in logic; some view his social research, especially his work with questionnaires on lay people's and experts' perceptions of philosophical concepts and his use of statistics, as outside the realm of serious, professional philosophy; and still others see him as inappropriately conjoining his philosophy with activism. His breadth has even led a few of the more extreme critics to dismiss his work out of hand. Although some of the criticisms detailed above do have merit, in my view Naess gives the dilettante a good name.

To address this range of concerns, the *Selected Works* project was conceived. The project was the brainchild of Douglas Tompkins. "Miracle Doug," as Arne refers to him, is the founder of the Foundation for Deep Ecology and is himself a renowned climber and kayaker in addition to being a wildlands philanthropist who has helped protect immense tracts of land in Chile and Argentina, some as large as Yosemite. The *Selected Works* would have simply remained a "great idea" without Doug's generosity and support. The project was initiated in 1994 and commenced editorial work in 1996 under my direction.

In the introduction to his *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, and Sartre* (1968), Naess decries the condition whereby the philosophical life of an individual is set by the local philosophical scene, by provincial biases, or by what is easily accessible.¹⁶ Such accidents of envi-

SERIES EDITOR'S INTRODUCTION

ronment should not, in Naess's view, play a pivotal role in shaping a budding philosopher's development. I see the *Selected Works*, at least in part, as a response to this predicament.

The purpose of the *Selected Works* is to bring—for the first time—the full scope of Naess's philosophical contributions to the English-language audience in one collection of highly readable and meticulously edited volumes that adhere to the highest standards of contemporary academic philosophical publishing. The *Selected Works* is, however, by no means exhaustive; it is not a collected works.¹⁷ We have simply aspired through careful selection to offer a representative and relatively expansive collection of Naess's principal writings. As such, the *Selected Works* is the definitive repository of Naess's oeuvre, chronicling the development and progression of his thinking for scholars, students, and critics alike.

In the remainder of this essay, I attempt to sketch briefly one possible version of an intellectual biography for Arne Naess. I endeavor to trace some key influences on Naess's philosophical development, discuss the evolution of his philosophical outlook, and touch on the relevance and significance of each volume in the *Selected Works*. I close with a short note on our editorial approach.

From Scientism to Wisdom: Toward a Philosophy of Life

The philosophic researcher should be task-minded, not discipline-minded, and should follow his questions wherever they lead.

Arne Naess, "Norway"

Arne Dekke Eide Naess was born in 1912 in the dining room of a large house with a wild, expansive garden. The house was on the outskirts of Oslo in Slemdal, a short walk from where Naess lives today. Arne was the unplanned fourth child of a wealthy family from Bergen. Before he was a year old, his father, who was ill with cancer, had died. Overwhelmed, his mother, Christine, entrusted little Arne to the family's governess. This is where his first memories begin.

Arne speaks of Mina, his governess, endearingly. She is described as satisfying little Arne's every wish, be it procuring live flies for his bath or bringing a trunk filled with bottles on a family trip so that he could continue his water-play experiments. Sometime before Arne was four, Christine dismissed Mina, ostensibly for spoiling Arne too much. This initiated a deep

rift between Arne and his mother, which was never to be mended. It also set in place a sense of loss, alienation, and resistance to emotion that profoundly influenced Naess's early personal and philosophical development.

Significantly later, after an intensive six-day-a-week, fourteen-month psychoanalysis with Freud's noted collaborator Dr. Edvard Hitschmann, Naess came to understand his impenetrable shell that keeps others at arm's length (*Panzercharakter*, in Freudian terms) as resulting from a reaction to his mother's unreliability and emotional hysteria. His effort to keep his mother at a distance morphed into a general aloofness and distancing. The adolescent Arne began to favor an "objective," bureaucratic approach to language. He saw art, music, and poetry as being seduced by emotion, by beauty and form, but viewed science and philosophy as realms from which such emotions should be banished. This prejudice would take decades to overthrow. At this time he also developed a single-mindedness and resistance to inconvenience and pain that to this day make it easier for him to concentrate and focus. As Hitschmann pointed out, however, this inward turn has a flip side, a certain self-destructive or masochistic bent that was later to plague him, particularly in his relationships with women and his children.

Much of Arne's early childhood was spent at the seashore, and this is the period in which his interest in nature and experimentation began to flourish. Feeling somewhat distanced in his relations with people, he identified with nature, especially little sea creatures. He waded in shallow water for hours, inventing experiments to test nascent hypotheses about the behavior of small sole, tiny translucent shrimp, and crabs. He describes these experiments as engendering an early enthusiasm for diversity and a tendency to suspend judgment on the nobility or status of different beings. He loved these creatures for their unique qualities and their amusing adaptations and limitations. They inspired a certain egalitarianism, which took hold and later influenced his philosophical approach in profound ways.

Young Arne was restless. He had an early penchant for "collecting" and organizing large groups of numbers, stones, and stamps. He started climbing trees in the family's little "wilderness" before he was five and soon progressed to big firs and spruces. He found that he enjoyed being able to watch people from above. Arne outgrew trees fast. His desire for perspective and the opportunity to survey broad areas was rapidly transferred to mountains. At the age of five, he began going to his mother's small moun-

SERIES EDITOR'S INTRODUCTION

tain cottage in the town of Ustaoset, high in the Hardangervidda between Oslo and Bergen. By the age of eight, he had adopted Hallingskarvet, a bread-loaf-shaped mountain about three and a half hours' walk from Ustaoset, as his surrogate father. In his teenage years, this obsession for expansive perspectives translated into a lifelong passion for mountaineering. When Naess was sixteen or seventeen he climbed the 106 tallest mountains in Norway. It was around this time that he was first introduced to Spinoza's *Ethics* by a Norwegian Supreme Court justice that he met in the mountains. Naess's desire for a broad and open perspective, for seeing things in totalities (god's-eye view), translated to his studies. Young Naess read widely in economics (especially value theory), science, philosophy, history of philosophy, and the Earth's biological history.¹⁸ This commitment to cultivate an ever-expanding perspective would later potently influence his approach to philosophy.

Arne's youth was spent captivated by piano, study, and mountains. His decade-older brothers took it upon themselves to toughen up their timid younger brother, as well as introduce him to the ways of the world and scholarship. When Arne was only eight, his eldest brother, Ragnar, left for America to study for a Ph.D. in chemistry at MIT. Ragnar later went on to receive one of the Harvard Business School's first degrees and became a successful stockbroker in the United States. Erling studied economics and went on to create an international shipping empire; he became famous for his assistance to the Norwegian government-in-exile during the Nazi occupation. His sister, Kiki, married a German doctor and after the Second World War returned to Norway to become a physical therapist. From Kiki he learned the power and significance of offering encouragement to others. During his early years and well into adulthood, Arne's tight-knit relationship with his siblings provided security and support for him to "find his own way"—*sva mārga*, to use one of his favorite Sanskrit terms. Although he tended not to seek their financial assistance, his wealthy and generous brothers offered a sense of comfort, safety, and the occasional extravagance, which in later life made it easier for him to live his bon mot, "simple means, rich ends."

Naess studied philosophy, mathematics, and astronomy at the University of Oslo. At nineteen, after completing the equivalent of an undergraduate degree, he left Oslo to continue his studies in Paris. Naess was put off by the adoration Bergson received in Paris, but ultimately left to seek

broader vantage points, cheaper living, and better climbing opportunities. After completing two master's theses at twenty-one, one exploring discussion about the concept of truth and the other exploring the use of behavioral psychological principles to judge truth validity, Naess left Oslo again, this time for Vienna. In Vienna he took master classes in piano, where, following his trickster nature and as a response to the strict taskmaster Fuchs, he "learned" new material. When he ran out of pieces he had long since mastered, he quit. Thinking that it was necessary for philosophers to have high levels of self-knowledge, he underwent intensive psychoanalysis with Dr. Edvard Hitschmann. As a part of that process he assisted with the treatment of patients in a psychiatric hospital and developed tremendous empathy for the suffering of humankind. While in Vienna, he was also warmly welcomed at the famous Schlick seminar.

The logical empiricists' friendly, equiminded approach to discussion made a great impression on Naess, but he was not equally affected by their ideas.¹⁹ The young Arne was impressed by the preciseness, empirical nature, and lack of emotion in science—he wanted to practice philosophy with a scientific bent and he wanted to test philosophical hypotheses with experiments. He was already interested in perennial philosophical problems and did not believe that most of them were ultimately pseudoproblems that could be solved by investigating inconsistencies in language. His most significant philosophical issue with the logical empiricists was not that they were empirical, although he believed they were misguided in thinking that any philosophical problem could be wholly empirical, but that they were ultimately antiempirical in their belief that a logical grammar of language was more suitable for investigating the use of terms than statistical analysis of their actual use. Naess's detailed critique of the logical empiricists' position and reflections on his personal experiences attending the Schlick seminar appear in volume VIII. In this critique, Naess expresses a concern that in their interpretation of terms, many philosophers (not just the logical empiricists) were artificially constricting the range of possible interpretations and thus unintentionally reducing potential insights regarding the diversity of tenable positions on problems of vital concern. This perspective presaged his later views, particularly those expressed in *Interpretation and Preciseness* (SWAN I), and his later approach to cultural anthropology and philosophy of science. Naess sums up his general perspective on the state of philosophy at the time with the following remark: "The

turn of (Western) philosophy in [the twentieth century] towards language rather than cosmos, towards logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind-alley."²⁰

While in Vienna for fourteen months in 1934 and 1935, Naess made final revisions to his doctoral thesis, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior).²¹ Although Naess drew inspiration early on from Russell and Whitehead, his doctoral thesis can be seen, in part, as support of the American Pragmatists (James and Dewey) in opposition to Russell and early Wittgenstein. According to Dewey, the main purpose of his philosophical writings was "to reintegrate human knowledge and activity in the general framework of reality and natural processes."²² Naess did just this by creating a radical and unique approach for exploring how high science is performed, a sort of science of science. At this point, Naess believed it was possible to use such an approach to obtain a complete account of all science within one system. Inspired by the ethologist Uexküll's "special biology" (*Umweltforschung*), Tolman's "objective" behavioral psychology ("molar" behaviorism), and the cultural anthropologist Malinowski's work on speech and nonverbal behavior, Naess took on the standpoint of a neutral, nonparticipant spectator and outlined a program for an empirical metascience of science, an ethological approach to epistemology of science.

Naess used the idea of a dispassionate visitor from another solar system coming to study Earth-based scientists to demonstrate the possibility of completely describing both the activity of researchers and the contents of knowledge without drawing on the subjective models that governed traditional epistemology and presupposed knowing subjects or minds. The idea was to study or rather "witness" science similar to the way experimental psychologists study rats, but without falling into the trap of imposing their own experience of reality and their preexisting conceptual models of reality ("maze epistemology"), or their scientific pretensions. In the view described in *Erkenntnis*, knowledge is cognition—it is an activity with intention—and this helps to dismantle the subjectivist dualism between the content of knowledge and the activity of research. Naess's interest was in describing these patterns of research activity. He argued that the *terminology* associated with scientific activity—which is bound to the subjective-reality model—changes in leaps and bounds, not the *patterns of research activity*, which are in constant, but gradual, flux. With this argument that

change in science happens gradually, by generalization and differentiation, Naess foreshadowed his response to Kuhn well before *The Structure of Scientific Revolutions* was published in 1962.

With *Erkenntnis*, Naess also anticipated ideas that later became prominent in linguistic philosophy, such as the importance of ordinary language over formal systems and the importance of using observation of contrasts and discriminations to build up understanding of systems. In the end, presaging his own radical pluralism to come, Naess seems to relax his early position on the importance and possibility of creating a metascience of science from the “far outside” and ultimately comes to view subjective and behavioral models as two different point-of-departure formulations in an indefinite plurality of equally valid approaches for a metascience of science. This refined perspective is taken up in Naess's 1965 article “Science as behavior” (in SWAN IX), which returns to the prospects and limitations of creating a behavioral metascience to study the scientific enterprise, but this time from the “near outside.”

At age twenty-four, after receiving his Ph.D. from the University of Oslo for his work on science as behavior, Naess returned to his interest in the problem of truth. A particular concern was the inadequacy of philosophers' intuitive methods for capturing how lay people conceived and used the term *true*. In 1937 and 1938 he developed and tested an empirical approach for using questionnaires and statistical analysis to investigate non-philosophers “commonsense” views on the notion of truth. He then related these notions to philosophers' theories of truth. Naess found an amazing diversity of views among the amateurs. He also found that their views, although typically devoid of philosophical pretensions, generally covered the views represented by professional philosophers. This work elicited substantial controversy, most of which came from philosophers who viewed it as undignified to use questionnaires and statistics to investigate one of the great problems of humanity. Naess's results were published as “*Truth as Conceived by Those Who Are Not Professional Philosophers* (1938). A summary of this work is presented in Naess's “Common Sense and Truth” (in SWAN VIII). Naess's continued application and refinement of these techniques would evolve into empirical semantics.

In 1937 Naess fortified his lifelong fascination with the arctic climate Hallingskarvet by building Tvergastein, his now-famous rustic and remote hut, at its base, a three-and-a-half-hour trek from the train station at Us-

SERIES EDITOR'S INTRODUCTION

taoset. He outfitted the hut with Rube Goldberg oil lamps that also served as stoves for warming tea and with an eclectic library of teach-yourself language manuals, Sanskrit-English dictionaries, astronomical and wildlife field guides, novels by Dostoyevsky and Ibsen, letters of Spinoza, and a complete philosophy library. Following his passion for amateur science he also created “institutes” of petrology, chemistry, zoology, hydrology, and botany at Tvergastein. Naess has written the bulk of his work at Tvergastein and spent the equivalent of about twelve of his ninety-two years living there. The enormous open views at Tvergastein afforded Naess the distance and perspective he so craved while insulating him from philosophic fashion and dogma. Here he had the luxury, freedom, and good fortune to pursue his own interests free from the banalities and distractions of academic life. After completing what is now Tvergastein's main room, Naess went on to perform postdoctoral research at Berkeley (1938–39) with the pioneer of empirical psychology, E. C. Tolman. At Berkeley, he went from studying the behavior of rats faced with many possible alternatives to studying the behavior of the scientists studying the rats.

Naess returned to Oslo in 1939 to be appointed to the University of Oslo's Chair of Philosophy at the age of twenty-seven. On April 9, 1940, German forces invaded Norway; it would remain under Nazi rule for the next five years. This was a harrowing time for academics throughout Europe. Arne tried to maintain his unruffledness, pouring himself into research and curricular reform initiatives intended to widen and expand the perspective of university undergraduates. He tried to stay at Tvergastein often, and this afforded him some peace and solace in a world of great tension. Before long, however, even he was drawn into the resistance movement. In the fall of 1943 he played a central role in foiling a Nazi attempt to deport University of Oslo students to concentration camps for “reeducation.” The University was subsequently closed and Naess became even more committed to the resistance movement and his research. By this time he had developed great admiration for Gandhi's catalytic 1930 *satyāgraha* campaign, the march to Dandi in protest of the British salt tax. Naess was greatly impressed with Gandhi's idea of trying to meet one's opponent in a manner that would calm passions and facilitate truthful communication. He thought such an approach could have had a significant effect on quenching the Nazi expansion, *if* the necessary infrastructure to support *satyāgraha* had been created in European countries. After the war,

Naess used these insights in his efforts to bring together suspected torturers and the families of torture victims to gain a sense of closure on the fate of their loved ones—and to avoid having the “traitors” subjected to equally horrid persecution. In 1948 Naess was invited to be the scientific leader of a new UNESCO project created to explore ideological controversies between the East and the West. He was soon off to Paris again, this time to pursue his interest in using philosophy to address questions of social and political importance.

The Cold War was a tinderbox and two core ideological conflicts revolved around use of the terms *democracy* and *freedom*. Naess was asked to address both but countered that UNESCO's requirement that he deliver a report within one year made it essential for him to consider *democracy* first. His goals were to clarify what people mean when they use the term *democracy* and to understand the causes of ambiguity and confusion that result from its use. After an extensive literature review, which chronicled historical usage of the term, Naess and his assistant, Stein Rokkan, prepared a thirty-question survey that was distributed to almost 600 international experts in the fields of philosophy, law, history, political science, sociology, economics, communications, and logic. Naess used the roughly 100 replies to create an empirical study of “agreements” and “disagreements.” The study demonstrated *democracy's* richness, diversity, and multiplicity of meanings and thus undermined its misuse in both the East and the West. This incited detractors from every ideology, who roundly criticized the resulting report, *Democracy in a World of Tensions*, which according to Naess “was promptly sold out and never reprinted by UNESCO due to the politically dangerous character of its items.”²³ Naess's “Analytical Survey of Agreements and Disagreements,” along with two other pieces on ideological convictions and rationality, appears in SWAN IX.

The UNESCO democracy study was the first and last international, large-scale application of Naess's empirical semantics approach. He was originally interested in doing another study on “cultural diversity,” but neither this nor the “freedom” study came to fruition. Naess learned—much to his chagrin, and as his superiors had warned—that UNESCO was a place for writing reports; it was no place for conducting research. Naess's frustration with the UNESCO experience and his wanderlust for the perspective of mountains led him to daydream first, and then to “pursue non-essentials”:²⁴

SERIES EDITOR'S INTRODUCTION

The arguments against abandoning the imaginary joys of the Himalayas for an actual expedition seemed strong to me, and so they still do. But in the autumn of 1948 the longing for the mountains pushed aside all sensible considerations. For the first time since I was twelve years old, I had to do without a summer holiday in the mountains. The safety valve guarding one against exaggerated climbing expeditions was thus removed. Added to this came the great disappointment in my own work. Lured by UNESCO's plans of philosophical research into international ideological conflicts, I had been tied up in Paris for nine months. Such large-scale extravagant schemes prove, however, impracticable. Too much nationalism and too little belief in research prevented UNESCO from getting the number of nations to subscribe to such long term schemes. By the way of compensation, I indulged at night in delightful trips to the Alps. As the situation got worse, this was, however, not sufficient compensation; the material was exhausted. Then my fantasies took me to the Caucasus. Later I had to go all the way to Persia, Afghanistan, Hindu Kush and India, and so I was committed.²⁵

Although Naess's research interests and total view continued to evolve after 1953, the general philosophical approach of the mature Naess, outlined at the beginning of this essay, was basically in place. Naess has described his philosophical work as falling into four periods or phases. From the mid-1930s until about 1940, he focused on philosophy of science. Then until about 1953, he concentrated on empirical semantics. A short period, surrounding the publication in 1968 of his major work on the zetetic scepticism of Pyrrho, ends when, at the pinnacle of his philosophical career, he sought early retirement in 1969 to devote himself more fully to ecological issues and activism. Naess has commented that this effort to be more actively engaged in social and political conflicts reflects his desire "to live rather than function." This view adequately reflects coarse, general trends, but it fails to do justice to Naess's philosophical approach, which has him mine a larger range of topics and return to them in a helical fashion throughout his life. I would rather describe his work as falling into thematic areas that were picked up, sometimes put on ice, but returned to periodically throughout his life. Although I concur that the period after his formal retirement can be seen as emphasizing ecological philosophy and activism, the two decades between 1960 and 1980 also represent a period of considerable productivity on conventional academic philosophical topics. It was in those decades that Naess produced important work, especially, on

scientific and cultural pluralism, Gandhi and Spinoza scholarship, history of philosophy and philosophy education, and normative systems theory. He has written on a wide range of important philosophical topics even into the 1990s and beyond, during which time he produced, among other works, his *Life's Philosophy* (2002; coauthored with Per Ingvar Haukeland), introductions to the philosophy of Gandhi (2000) and Spinoza (1999), and *Introduction to General Relativity and Its Mathematics* (1998; coauthored with Øyvind Grøn).²⁶ An adequate sketch of Naess's subsequent research interests and philosophical development can be gleaned from the following brief discussion of the volumes in the *Selected Works* and the discussion, at the end, of how his earlier work figures into the evolution and exegesis of deep ecology.

Naess's best-known philosophical work is likely *Interpretation and Preciseness*, published in 1953 (SWAN I). It is an attempt to convince the world of analytical philosophy about the types of approaches that are necessary, from the standpoint of a radical empiricist, to adequately interpret terms and point-of-departure statements (T_0 statements), given the manifold of plausible interpretations. It highlights the role and potential of experience in relation to intuition and reflection by requiring that every direct or implied hypothesis regarding the actual use of terms, phrases, or sentences be testable. In addition, it responds to the ostensibly antiphilosophical sentiment in *Erkenntnis* by clarifying the function of and relationship between point-of-departure statements and precizations. In Naess's semantics, the most general statements, T_0 statements (words or sentences), are phrased in ordinary language and are intended to be philosophically neutral. T_0 statements serve as points of departure for investigations of possible interpretations. When a new interpretation of an expression eliminates some of the ambiguity of a preceding interpretation, without adding any new ambiguity, it is said to be a "precization." Thus, a sentence T_1 is more precise than a sentence T_0 when every plausible interpretation of T_1 is also a plausible interpretation of T_0 but at least one plausible interpretation of T_0 is not a plausible interpretation of T_1 . This process of using successive differentiation to better understand people's interpretations of terms, phrases, or sentences can go on almost ad infinitum; it is limited only by time, resources, imagination, and willing test subjects. With this process, however, Naess has created a formal approach for classifying different statements (interpretations) based on users' "depth of intention," the point at which they no longer, explicitly or implicitly, accept or embrace higher levels of precization. A focal point is

SERIES EDITOR'S INTRODUCTION

Naess's approach of directly employing surveys to explore systematically and empirically the meanings of terms, phrases, or sentences based on their occurrences. Naess also created a formal procedure for comparing occurrences, both interpersonal and intrapersonal, that involves performing tests for different forms of synonymy. Naess has applied his empirical semantics approach to explore the meanings of "truth," "democracy," "it is the case," "certain," "perfectly certain," and "extremely probable" (see SWAN VIII for additional details on and applications of empirical semantics).

In *Scepticism* (SWAN II), published in 1968, Naess takes on the generally accepted position that scepticism, if widely embraced, leads to the intuitively false conclusion that we cannot know anything. Naess explores the variety of historical interpretations of scepticism in light of Sextus Empiricus's outline of Pyrrhonian scepticism. Three categories of philosophical positions on the question of truth are considered: Dogmatists claim at least one truth, Academicians negate the possibility of finding any truths, and Pyrrhonists neither assert that they have found any truths nor assert the impossibility of finding one. Naess takes a sympathetic view of this last group, arguing that this form of zeteticism can represent both a viable philosophical position and a way of life that supports positive mental health. What ultimately sets this position apart is not that supporters are fundamentally opposed to making acts of assertion, to stating that "something is the case," but that they do not make such assertions with the conviction of truth. Naess also uses empirical semantics to demonstrate support for this position on rational and epistemological grounds. Distinguishing between one's philosophical view and the necessity of firm, socially responsible action in everyday life, he also responds to the common notion that this radical nondogmatism generally leads to paralysis of action. In the end, Naess argues that adopting this updated view of Pyrrhonic scepticism could lead to quite the opposite, a more open-minded approach to philosophy and life. Further elaborations on particular aspects of Naess's Pyrrhonism along with a response to Rescher's reappraisal of scepticism appear in SWAN VIII.

Which World Is the Real One? (SWAN III), which was first published in 1969 and revised in 1982, is, in part, an attempt to reinvigorate appreciation and study of the broad variety of philosophical outlooks and total views that exist in Chinese, Indian, Greek, Western, comparative, and recent philosophy. It makes use of Naess's empirical semantics, developed in *Interpretation*

and Preciseness, to argue that it is an illusion to assert that combined scientific and philosophical or "purely" philosophical syntheses of such total views can exist. Naess argues that the results of science cannot be integrated into any single world picture, in part because such attempts at synthesis are necessarily fragmentary and because valid multiplicities of syntheses exist. He also takes up the question of the comparability of total views. Such comparisons, although important, are inevitably shaky because, despite admirable aspirations for standing back to obtain a meta-perspective, real people can never totally throw off their own total views; regardless of how explicit those views may be or of how conscious of them their holders are, biases are unavoidable. We always have our own perspective to contend with. For Naess the inevitable conclusion is that pluralism is inescapable and nothing to lament. He combines these points of view with a discussion of cultural anthropology to argue for the critical importance of supporting the flourishing of rich cultural diversity. Additional articles elaborating themes related to the significance of maintaining cultural diversity and its relationship to ecological sustainability appear in SWAN X.

In *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), published in 1972, Naess suggests that scientific theories must be understood in the wider context of the plural rationalities from which they spring. Science is not autonomous. Nor can it be seen justifiably as arising independently from the general enterprise of building philosophical systems. Furthermore, the relationship of models to reality is always indirect. This volume should be seen as an effort to erode the popular misconception of science as infallible and a viable surrogate for religion, not as an attempt to build a unified theory of science within one system, which Naess had long since rejected. Because no theory can ever be either fully verified or falsified, there exists a significant freedom of choice in both modes of exploration and theories that one can tentatively adopt. The notion of "fundamental theories" is immediately called into question. As the undemonstrated (and often undemonstrable) assumptions upon which theories rest are changed, a huge multiplicity of possibilities for future theory development arises, thus possibly helping to inspire a renewed enthusiasm in science by broadening our concept of rationality and restoring the role of imagination. Articles extending or elaborating on the ideas in *The Pluralist and Possibilist Aspect of the Scientific Enterprise* appear in SWAN IX.

Naess's third book on Gandhi, *Gandhi and Group Conflict* (SWAN V),

SERIES EDITOR'S INTRODUCTION

was published in 1974. This book develops an intellectually rigorous presentation of the theory of *satyāgraha*—the way of militant nonviolent resistance—as a strategy for conflict resolution. This work is a paradigmatic example of Naess's approach to research and writing. As the eminent Norwegian social scientist and peace researcher Johan Galtung has suggested, Naess's 1955 *Gandhis Politiske Etikk* (Gandhi's political ethics)—with Galtung—and his 1965 *Gandhi and the Nuclear Age*, along with his articles that analyze or extend on Gandhi's work (see SWAN IX and X), act as exercises or drafts for this, his major work on Gandhi.²⁷ Using Gandhi's own recorded accounts, Naess explores the norms and hypotheses tacitly employed by Gandhi in his nonviolent campaigns and then uses these to create the first philosophical and logical systematization of Gandhi's approach to militant nonviolence. A careful investigation of Gandhi's two ultimate norms (as interpreted by Naess), "Seek complete self-realization" and "Seek truth," and his belief in *advaita* (nonduality), along with a consideration of their parallels to Spinoza's unity thesis, will reveal interesting insights into Naess own characterization and use of "Self-realization!" as the single ultimate norm of his Ecosophy T. Naess also considers Gandhi's approach to nonviolent conflict resolution in light of contemporary reactions against the use of nonviolence by Frantz Fanon, Malcolm X, Stokely Carmichael, C. V. Hamilton, and Sartre. He then examines Gandhi's ideas and intentions regarding group conflict in light of the ideas and intentions underlying other modern philosophies of conflict, including those of Luther, Nietzsche, Tolstoy, and Jaspers.

In *Freedom, Emotion, and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics* (SWAN VI), Naess uses symbolic logic to present a formalization and partial reconstruction of a small but important part of the *Ethics*. Spinoza's system is embedded in the seventeenth century and expressed in Medieval Latin. Two of Naess's goals are to bring empirical analysis to bear in trying to interpret and update Spinoza's system and to make Spinoza's insights more accessible and relevant to contemporary readers. To perform his reconstruction, Naess draws heavily on a small book he produced in 1962, *Equivalent Terms and Notions in Spinoza's Ethics*, which lists and discusses 243 equivalences that are directly asserted or suggested by Spinoza in the *Ethics*, according to Naess.²⁸ Accepting the transitivity of the equivalence relations as a general rule, Naess argues that a vast array of structural relations can be elucidated (many of these are often only suggested or implicitly asserted by

Spinoza). One of Naess's key conclusions is that every living thing is to some extent "in itself" and to some extent "in something else" due to the presumed gestalt nature of reality. Another is that the terms *substance*, *attribute*, *God*, *mode*, and *Nature* are "expendable"; Spinoza's basic nondualism is made clearer by Naess. A third conclusion is that *to be active* and *to understand* cannot be systematically distinguished in the *Ethics*. This notion, which has important implications for philosophy of science, is also embedded in Naess's conclusion in *Erkenntnis* that knowledge is cognition—the content of knowledge and the activity of research cannot be cleanly separated. Naess uses his analysis to explicate three main themes of Spinoza's system: the importance of a notion of uncoerced freedom (not coerced by externals), the importance of developing and acting on strong emotions to make progress in achieving higher levels of freedom, and the importance of joy that activates the complete person (as opposed to joy that simply activates part of the body or the soul). By clarifying the semantic structure of a central part of the *Ethics* with his own logical structure, Naess explains that there exists a wide variety of possible interpretations of the contents of the *Ethics*. Articles on Spinoza's determinism and its relationship to freedom, Spinoza and Māhāyana Buddhism, "Spinoza's Finite God," and other Spinoza-related topics appear in SWAN IX. Articles that explore Spinoza as an inspiration for deep ecology appear in SWAN X.

The English translation of *Communication and Argument: Elements of Applied Semantics* (SWAN VII), which was first published in 1966, is largely a popularization of the central ideas in *Interpretation and Preciseness*. The English edition is a somewhat watered-down version (no exercises) of the Norwegian edition that from 1941 to 1969 was used by nearly 100,000 university students in the *examen philosophicum*. Its purpose, to quote the *Times Literary Supplement*, is " . . .to teach people in a democratic society to think clearly, coherently, and above all responsibly." Naess's hope is that teachers use controversial examples from current events—the more emotional the better—to confront students with their own confusion and encourage them to strive for higher levels of depth of intention. The final chapter outlines six "Gandhian" rules of effective discussion, which emphasize avoiding six forms of "irrelevance in discussion."

The first two volumes of selected papers (SWAN VIII and IX) contain important material that is not covered by the preceding volumes, material that complements them, or material that builds on or reevaluates positions

SERIES EDITOR'S INTRODUCTION

taken earlier. Volume VIII includes sections on "Empirical Semantics and 'Truth,'" "Zeteticism," "Empiricism, Possibilism, and Pluralism," and "Metaphysics, Morals, and Gestalt Ontology." Volume IX includes sections on "Democracy, Ideology, and Rationality," "Philosophy of Science," "The Philosophy of Peace, Gandhian Ethics, and Communication," "Spinoza," and "Philosophical Development, Environment, and Education" (which includes an autobiographical article describing key influences in Naess's philosophical evolution, "How My Philosophy Seemed to Develop" and an interview, "Deep Ecology and Education"). A number of the especially significant articles have already been referred to, where relevant, in the discussion of Naess's philosophical evolution; other articles are discussed in the notes.

Today, Naess is, perhaps, best known for his "deep ecology" writings, the topic of *Deep Ecology of Wisdom* (SWAN X). This work began with a short unpublished paper written in 1965, "Nature ebbing out" (in SWAN X), and continues to this day. As the primary architect of deep ecology, Naess has more than seventy-five published articles and book chapters and more than sixty unpublished pieces on this topic. His only book-length discussion of deep ecology began with a short mimeograph, *Økologi og Filosofi* (Ecology and philosophy), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi, Samfunn og Livsstil* (Ecology, community, and lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. This book has not been included in the *Selected Works* because it is widely available and currently in print.

Volume X is the first comprehensive collection of Naess's work on deep ecology—it includes a broad array of articles on its history, influences, theory, development, practice, and prospects. This volume shows how deep ecology represents the integration and culmination of Naess's lifelong interests in philosophy, social research, activism, science, and nature. It demonstrates how Naess, in his explication and elaboration of deep ecology, draws extensively from both his life experience and his research on empirical semantics, scientific and cultural pluralism, Pyrrhonic scepticism, Spinozistic nondualism and activeness in relation to problems, gestalt ontology, normative systems theory, total views, and Gandhi's concepts of self-realization and nonviolent communication. Volume X also shows how Naess's approach to deep ecology has unfolded over time, with substantial emendation, in part as a response to the worsening ecological crisis, in part to answer criticisms that deep ecology was turning into a cult or religion,

and in part to address the considerable confusion and controversy that arose from his use of provocative terminology and philosophical vagueness.

Ever since he coined the term *deep ecology* with his now famous paper "The shallow and the deep, long-range ecology movement: A summary," (in SWAN X) given at the 1972 Third World Future Conference in Bucharest, Naess's central concern has been to use philosophy and philosophical thinking to help humans overcome the ecological crisis and, ultimately, to restore the Earth to a state of rich and flourishing biological and cultural diversity (see volume X). A basic premise is that some ethical norms, particularly those grounded in spontaneous experience, can be tentatively accepted as objectively valid. An example for Naess would be the statement that "Every living being has an equal right to live and flourish, *in principle*." This statement in no way denies that maintaining our existence necessitates killing living beings. Another key premise is that the human potential for caring is not static or limited—it can be both extended and deepened. The ecological crisis is embedded in an ecocultural crisis. Its resolution will necessitate cooperation and collaboration among the peace, social justice, and ecology movements.

Naess does not see himself as "inventing" deep ecology. Rather, he gave a name and a philosophical framework to a minority tradition, a nascent social movement that has been with humanity since at least Buddha, Chuang Tzu, Saint Francis of Assisi, Thoreau, John Muir, and Aldo Leopold, and is epitomized by Marjory Stoneman Douglas's 1947 *Everglades: River of Grass* and subsequent crusade to save the Everglades.²⁹ This movement finally came of age in the contemporary era after Rachel Carson's *Silent Spring*. Naess's work on "deep ecology" can be subdivided into three main thematic areas.³⁰

What I refer to as Naess's deep ecology approach (deep ecology as an ecophilosophical approach) represents his contributions to deep ecology theory—it is essentially an outline of a general philosophy of life, which draws considerable inspiration from Gandhi and Spinoza. The focal points are encouraging ultimate beliefs that support our capacity to identify with all living beings and Naess's general, pluralistic, normative systems-based strategy for assisting individuals in the process of weaving their ultimate beliefs, descriptive and prescriptive premises about the world, ecological science, and philosophy into systematic conceptual structures for relating to the world—ecologically inspired *total views* or *ecosophies*.

His work characterizing and supporting deep ecology as an international, grassroots social and political movement, along with his work enter-

SERIES EDITOR'S INTRODUCTION

ing into the fray, addressing conflicts, implications, and practical applications of the theory, falls into the realm of contributions to the “deep ecology movement.” Supporters of the deep ecology movement are not united by a commitment to deep ecology as an academic ecophilosophy (which they may not be familiar with or embrace), but by their willingness to endorse the eight-point deep ecology platform, prepared by Naess and Sessions in 1984.³¹ Finally, work discussing his personal systematization of a deep ecological total view falls into the realm of “Ecosophy T.”

Naess coined the terms *deep ecology* and *shallow ecology* in 1972 to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis. In proposing the deep/shallow contrast, he made a technical semantic distinction directed at our level of problematizing—the extent to which we can, and do, coherently and consistently trace our views, practices, and actions back to our ultimate beliefs or bedrock assumptions. Naess starts with a premise, which he has investigated empirically, that at the level of their ultimate beliefs, people generally identify with and appreciate nature. He then uses this to argue that many regrettable environmental decisions are made in a state of “philosophical stupor,” in which narrow concerns are confused with, and then substituted for, more fundamental ones.

The “shallow,” currently more influential approach to environmentalism is identified with treating the symptoms of the ecological crisis, such as pollution and resource degradation. This reform-oriented approach is grounded in technological optimism, economic growth, and scientific management, not in ultimate premises that plumb the relationship between people and nature. It thus ultimately fails to address the philosophical, social, and political roots of the ecocultural crisis.

The “deep” approach, on the other hand, while in no way discounting the exigency of addressing pollution and resource degradation, adopts a broader, long-term, more sceptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach’s proposed solutions take into consideration the nature of reality and the complexity of the problems its adherents hope to rectify. Stressing the importance of addressing the fundamental roots and coevolving causes of the ecological crisis, deep ecology posits that along with humans’ special capacities for reason and moral consciousness come special responsibilities,

particularly in relation to the flourishing of nonhuman life and the ecocultural sustainability of the planet.

The deep ecology approach calls for expanding our sphere of concern to all living beings—charismatic or dull, gargantuan or tiny, sentient or not. It acknowledges that every living being has value in itself and views the flourishing of nature and culture as fundamentally intertwined—as part of one reality. This *wide-identification* is characterized by the perception that all life is interdependent; common goals bind all living beings to the life process. In Naess's view one can arrive at wide-identification by drawing on a broad diversity of philosophical or religious ultimate premises, with roots ranging from Christian Stewardship to the Gaia Hypothesis to Naess's own ontologically inspired "Self-realization!" In its most expansive form, wide-identification is the intuition that nature's interests and our own coincide, as with Naess's "Self-realization!"—something akin to a blending of the Hindu *ātman* with a biospherical Pareto-optimality principle. Simply stated, this principle asserts that the increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other individuals or species.

By juxtaposing these two, almost caricatured perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The central premise is that society's potential to overcome the ecological crisis rests on guiding discussion and debate to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and their actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an individual's actions and his or her fundamental beliefs, while possibly engendering serious ancillary conflict along the way, will ultimately generate progress toward ecocultural sustainability.

Naess contends, as I have pointed out earlier, that humans act as if we have total views whether or not we make such structures explicit. Because our decisions regarding society and nature are guided by our total views, Naess maintains, we *should* attempt to articulate them. By making these structures explicit, we expand both our opportunities for fruitful debate and

SERIES EDITOR'S INTRODUCTION

interchange and our possibilities for creating policies that are consistent with our collective ultimate beliefs. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending "rights" to certain nonhuman life-forms or grading intrinsic value. The ontologically inspired deep ecology approach attempts to counter the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudo-rational thinking.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of "depth." In the context of deep ecology as an ecophilosophical approach, depth refers to both the general level of problematizing we employ in seeking out the underlying, co-evolving causes of the ecocultural crisis and the extent of our willingness to consider an expansive array of social and policy responses, even if they necessitate changes that constitute a radical departure from the status quo. Rather than calling for a new environmental ethic or a radical change in fundamental values, Naess's approach to ecophilosophy centers on transforming practice and policy by challenging us to develop more thoroughly reasoned, consistent, and ecologically inspired total views. This work represents a culmination of his effort to integrate reason and emotion. He has created the foundation for a new and promising human/nature relationship that positions humans as plain citizens with special abilities and unique responsibilities and nature as mentor, measure, and partner rather than servant. The current state of global ecological unsustainability has made Naess state that he is optimistic about the twenty-second century but pessimistic about the twenty-first; humans have a long way to go.

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of being inherently fascist, antihumanist, antifeminist, and against having indigenous peoples share wilderness areas with nonhuman life-forms.³² As the articles in volume X will show, none of these criticisms are compatible with a sophisticated reading of Naess's writings on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has clear answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three

key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not, on first principles, embrace wide-identification? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that lead to long-term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable means? Third, how can deep ecology help resolve conflicts in environmental decision making when those conflicts result not from pseudorational thinking but from genuine value conflicts?

Throughout this essay, I have tried to show how Naess's life of rich and varied spontaneous experiences and internal tensions have shaped not only who he is as a person, but also who he is as a philosopher. Viewed separately, Naess's contributions to academic philosophy, social research, and ecological philosophy and activism can appear discordant, dilettantish, and incoherent. When, through careful study of his helical progression, his philosophical and personal maturation, the pattern of the whole unexpectedly reveals itself as a unity, the whole suddenly becomes much more than the simple sum of individual books and articles. With the distance of a meta-perspective, Naess's collective philosophical contributions can be seen as a mosaic—as a superordinate gestalt, in some sense, as a rich and inspiring, but inevitably fragmentary total view. Naess has breathed life back into the study of philosophy by turning its study back to life. With his cultivation of a meta-perspective, a whole, new (old) approach to philosophy and way of seeing the world emerges. This richly patterned mosaic, by encouraging us to celebrate our freedom and affirm life, can help us to reshape our relationship to each other and the Earth in new and promising ways.

Conclusion

It was only as a professor that I became aware of the difficulties of suppressing the significance of the development of feelings in human affairs while at the same time worshipping reason. Both are constantly needed.

Arne Naess, *Life's Philosophy*

The ten volumes of this series (along with a subsequent volume of conversations between Naess and myself on deep ecology and his philosophy)

SERIES EDITOR'S INTRODUCTION

make available for the first time access to the breadth and depth of Naess's philosophical thought. Efforts to judge the significance of Naess's philosophical oeuvre—assertions made in the first sentence of this essay—can now be taken up on an informed basis. When embarking on this process, it may prove beneficial to reflect on Henry Adams's insight on the fundamental limitations of communication, and especially the limits of communicating one's fragmentary total view, "No one means all he says, and yet very few say all they mean, for words are slippery and thought is viscous."³³ Spinoza ends the *Ethics* with the following remark: *Sed omnia praeclara tam difficilia, quam rara sunt* ("But all very clear things are as difficult as rare").

In *The Radical Spinoza*, Wienpahl translates the phrase more literally than usual, rendering *praeclara* as "very clear" rather than the typical "excellent."³⁴ The quest for clarity is painful and difficult as well as amaranthine. The alternative, however, is to abandon joy and freedom and thus meaning. This is the essence of Naess's distinction between being an *academic philosopher* and being a *philosopher of life*, between merely *functioning* and *living*. Drawing inspiration from Spinoza, Naess has cultivated a practice of both integrating reason and emotion *and* transforming negative emotions into positive ones. His challenge is before us and the frontier is long—the choice, however, is ours.

Editorial Approach

Naess has always written books as if they were exercises for himself, tentative formulations that chronicled his views at that very second but were always subject to change. As I indicated previously, many of the prior editions of his books were poorly edited and sparsely documented. Existing bibliographies were incomplete, and indexes (in the rare cases in which they existed) were always inadequate. Quotations were often transcribed incorrectly and ill-referenced. In addition, the breadth of his work was enormous and sometimes repetitive. Arriving at a plan for a representative *Selected Works* that would have a consistent format and design was no easy task.

All the selections for the *Selected Works* were made in close consultation with Naess. I would prepare recommendations from my master bibliography file and then, whenever we disagreed, we would discuss the pros and cons of the piece and whether it was appropriate for inclusion (this ap-

proach proved particularly helpful when we reached the *Selected Papers* volumes). We immediately made a decision to exclude works that were widely available and currently in print. Other important works, such as his dissertation, and his major work on lay people's conception of truth, his work on the semantics of democracy and ideological controversy, and his contributions to history of philosophy were more difficult to exclude, but the nature of the project as a selected works demanded such tough choices. I was encouraged by the fact that Naess often published articles that summarized or updated earlier works. In the end, I was able to reflect a significant portion of the ideas and concepts in these excluded works by including articles of that type in one of the three *Selected Papers* volumes.

The details of editing proved more complex. Much to my chagrin, I very humbly learned how much work goes into a project of this scale and complexity. We decided early on that the level of editing required to bring the prior publications up to the high standards of contemporary academic philosophical publishing would necessitate revised editions. We also decided that since we were preparing revised editions and Naess was alive and could review the work, we would make the role of the editor invisible and not include tedious footnotes chronicling all the changes, however significant they might be. The historical significance, intricacy, and sheer magnitude of *Interpretation and Preciseness* (SWAN I) warranted special consideration. For these reasons, we decided that it would be best to prepare only an edited version for this volume and not attempt a complete revision as with the other volumes. In the early stages of the project Naess and I worked together closely, intimately. In my effort to eliminate errors and to enhance readability, flow, and clarity of argument, I brought Naess question after tedious question when I first embarked on the project (particularly when I was in Norway as a Fulbright Scholar in 1996). After working through several manuscripts, Naess decided to place the remainder of the responsibility for revising and editing the manuscripts in my hands.

We have made our best effort to reconcile inconsistencies, make corrections, and chase down incomplete bibliographic references (in most cases no bibliographies existed for the original works). I regret, however, that some imperfections remain. I am also responsible for any new errors that have been introduced—their existence, unfortunately, is unavoidable. I am, however, heartened by a conversation I had with Naess midway through the project, after he had reviewed several drafts of revised manu-

SERIES EDITOR'S INTRODUCTION

scripts. He commented that at least 90 percent of my revisions resulted in improvement and that no significant misinterpretations had been introduced. Given the nature and complexity of this project, that sounded like odds I could live with.

Acknowledgments

A project of this magnitude, by its very nature, represents the labor and love of an entire community. It could never have gotten off the ground, much less been completed, without a fantastic and deeply committed team. I have been blessed by the opportunity to work with, learn from, and receive guidance and support from so many talented friends and colleagues. It's been a wild ride; I owe you all a tremendous debt of gratitude.

First, the inspiration for the *Selected Works* and the majority of its financial support are due to the foresight and generosity of "Miracle Doug," Douglas Tompkins, president of the Foundation for Deep Ecology (FDE). Thanks for your vision, Doug. Quincey Tompkins Imhoff, former executive director of the Foundation (and current vice president of the board), also deserves recognition for her tremendous support during the early years of the project, as do program directors Jerry Mander and John Davis. Special thanks also go to Sharon Donovan, the Foundation's publishing manager, who in the project's final years has guided it through a long and sometimes circuitous path to completion. The Foundation has also always had an amazingly gifted and dedicated staff. At one point or another, many of its staff had a hand in helping this project along—offering assistance at a key point, a kind word, inspiration, or simply good cheer and a smile. Thank you, Denise Wilson, Debi Barker, Esther Li, Lizzie Udwin, Julie Lindow, Miyo Sakashita, and Emily Lydgate.

I was also supported by the Fulbright Foundation with a senior research/teaching fellowship at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. Additional support came from Western Michigan University. Special thanks go to WMU's dean of the College of Arts and Sciences, Leonard Ginsberg, and to my chair, Thomas Bailey. My colleagues at Western Michigan University also deserve thanks for their tolerance and succor while I focused all my available energies on this project. I am grateful for their flexibility and generous support. Wil Emmert, one of WMU's Research and

SERIES EDITOR'S INTRODUCTION

Program officers, also deserves a great thanks for his patience and skillful assistance.

The project has been blessed with a distinguished advisory board—Robert S. Cohen, Bill Devall, Alan Drengson, Ingemund Gullvåg (deceased), Per Ingvar Haukeland, Kit-Fai Naess, Nicolas Rescher, George Sessions, Michael Soulé, Douglas Tompkins, and Jon Wetleson. All of the advisers offered significant assistance in one form or another. Bob Cohen graciously shared his expertise and offered invaluable advice, encouragement, and support throughout the project. Bill Devall gave encouragement and helped bring volume X to completion by coauthoring its preface. George Sessions offered advice on the selections for volume X, provided guidance, and carefully reviewed a draft of this introduction. His suggestions greatly improved its flow and clarity. Kit-Fai Naess's tremendous moral support and great assistance in locating obscure documents and preparing bibliographies were invaluable.

Alan Drengson's contribution as a project adviser and in the project's final year as Associate Editor deserves special mention. At a crucial time, when the project was stalled in its later stages, Alan stepped up to the plate and played a key role in helping shepherd the project to completion. In particular, he took over most of the day-to-day project-coordination responsibilities for the final year of the project. He reviewed the copyedited manuscripts for volumes I, VIII, IX, and X, oversaw preparation of the author's prefaces to each volume and the editors' prefaces to volumes VIII, IX, and X, and reviewed the final manuscript proofs. This was not an easy task. I owe Alan a great debt for his fortitude, commitment, and generosity. For his contribution to the difficult and taxing responsibility of overseeing the final preparation of volume I, he has been credited as its sole editor.

I am lucky to have been supported by two astonishingly capable, committed, and patient project assistants. Kim Zetter played a critical role in getting the project off the ground and keeping it on schedule for the first three years. Later, Barbara Pijan helped steer the project back on track and over some awkward obstacles after it had run off course. Their talent and dedication played a major role in bringing to life the books before you. Thank you, Kim and Barbara, for your stalwart devotion to the project.

The beautiful and elegant design of the series is the work of Tomatsu Yagi and his nephew Akira Yagi. Ralph Fowler played a significant role in executing the Yagis' design and by filling in any missing gaps. Ralph also

SERIES EDITOR'S INTRODUCTION

performed the typesetting for volumes II–VII. The skillful and efficient crew at BookMatters performed the remainder of the typesetting. Katherine Silver handled the Brobdingnagian task of project management on volumes I and VIII–X and the last crucial stages of the project with aplomb, attention to detail, and fortitude.

The bulk of the project's copyediting was performed by the meticulous and supertalented Anne C. Collins, Ph.D., copyeditor extraordinaire. Additional copyediting was provided by Mary Anne Stewart and Kathy Walker. Indexing was performed by the immensely competent Nancy Mulvaney of Bayside Indexing Service, Julie Shawvan, and Leonard S. Rosenbaum. Proofreading was provided by Carrie Pickett.

Ingemund Gullvåg translated *Which World Is the Real One?* Iver Ørstavik provided the translation of "Experts' views on the inherent value of nature." The original editions of Naess's texts were keyed or scanned by the able and efficient crew at AgAccess—David Katz, Karen van Eppen, Jacob Katz, Rachna Boon, and Tim Rice. Additional keying of articles for the *Selected Papers* volumes was provided by Nancy Ropecka and Jane Drengson. Barbara Pijan, d Jones, Tony Hainault, and Debbie Reid deserve thanks for their careful and thorough transcribing of more than thirty-five hours of discussions with Arne Naess. Thanks are also owed to Tim Quick for his help with bibliographic research for volumes I and VIII–X, and to Kelly McKernan for assisting Alan with photocopying and faxing. In addition, a special thanks goes to Robert P. Goldman, Sarah Kailath Professor of Sanskrit and Indian Studies at the University of California Berkeley, for generously and graciously offering assistance on contemporary Sanskrit and Hindi terms.

I am grateful to the dedicated and very patient staff at Kluwer Academic Publishing. I am sad that our original editor, the immensely talented Annie Kuipers, who first recognized the importance of this project, did not live to see it come to print. Stephanie Harmon, Annie's replacement, worked closely with me on editorial matters and on finding high-quality recycled paper, cloth, foil, and other materials that meet the strict environmental considerations of FDE. In the final five years, the able and gifted Charles Erkelens was our editor.

Additional advice and moral support were provided by colleagues, friends, and family: Aimee Carroll, Kirsten Coyne, Paul Craig, Neal Goodwin, Byron Hahn, Ladislav Hanka, Alastair Hannay, Anna Leidberg-

SERIES EDITOR'S INTRODUCTION

Miron, Danny Moses, Richard Norgaard, Max Oelschlaeger, Brian Recht, Stephanie Sarvar, Ed Saxon, Geir Michael Sommerhein, Petter Sorum, and Kristin Walstad. Thanks for your efforts to coax me out of the cave.

Special thanks go to d and Reuben for their forbearance and succor. Someday, all too soon, Reuben will recognize that the invisible “work fairies” that were constantly pulling me back to my office don’t actually exist. I can’t wait.

Most of all, thanks to Arne Naess for placing his trust in me—it’s been a gift, something like an extended trudge up to Tvergastein, but without the fresh air and perspective. Taking on this project has been somewhat like receiving Pandora’s box as a present—all sorts of ills and plagues reared their heads along the way. I often felt that I was on a never-ending climbing descent in the night. I was always wondering about rappelling off my rope into the abyss.

The SWAN has taken flight, and I have landed on firm ground—I think? In all seriousness, I learned invaluable lessons. The more I worked through Arne’s writings, the more open-minded and optimistic I became. I found myself cultivating perspective and looking at the problems and challenges before me with fresh insights. I also found myself responding with more grace and equanimity in my efforts to counteract the numbing effects of contemporary society.

It is strange and ironic, however, that in being the series editor for the *Selected Works* of the father of deep ecology I spent so much time inside, chained to a desk. But this is part of the paradox of working with Arne Naess. I am reminded of one of my favorite poems—Gary Snyder’s “Axe Handles.” The last few lines read:

Pound was an Axe,
Chen was an axe, I am an axe,
And my son a handle, soon
To be shaping again, model
And tool, craft of culture,
How we go on.

And then it makes sense.

Harold Glasser
2004

Notes

1. In writing this essay, I found myself drawing on more than twelve years of friendship with Arne Naess. A simple bibliography could not do justice to describing how this subtle and multilayered gestalt has been formed. My perception of Naess and his work has been shaped by more than thirty-five hours of transcribed conversations between us, countless other conversations, letters, scraps of paper, e-mails, and Arne's copious annotations in my own books and articles. Camping trips, bouldering, hikes, and cross-country skis have also helped inform my understanding of Arne Naess the fiercely competitive, playful, elfin trickster, who springs to life in nature. I have benefited from three extended visits to Norway, including a Senior Fulbright at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. I have also spent other stimulating periods of time with Arne in Svalbaard, England, California, and the deserts of Arizona and Nevada. Finally, and probably most important, I have been inspired and forever changed by my own reading and editing of his work. In this regard, both previously published and unpublished materials have been influential in forming my own perspective on Arne Naess the philosopher. One key published source has been Naess's "How my philosophy seemed to develop," in *Philosophers on Their Own Work*, edited by Andre Mercier and Maja Svilar (Bern: Peter Lang, 1983), pp. 209–26 (in SWAN IX). Another source for insightful material on Naess and A. J. Ayer (as well as six of their contemporaries) is a book created from debates by philosophers for Dutch National Television. See, especially, "The glass is on the table: An empiricist versus a total view," in *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), pp. 11–68 (in SWAN VIII). Finally, additional perspective was offered by an article that discusses Norwegian philosophy from the end of the Second World War to just before 1980: Arne Naess and Jon Hellesnes, "Norway," in *Handbook of World Philosophy Since 1945*, edited by John Burr (Westport, CT: Greenwood Press, 1980), pp. 159–71.

On some of the fine points of this essay, I have benefited from extended conversations with my colleague and old friend George Sessions. I have also profited, over the years, from the significant literature that has been created to shed light on Arne's life and work. Many of the ideas and thoughts introduced in this essay—drawn from my own firsthand experiences with Arne—can also be found in these sources. In many cases, issues only touched on here are taken up in much more detail in those sources. Five key references for historical material on Naess and the evolution of his philosophical approach are identified below (two of which are videos). A wealth of additional material is available in the five festschrifts for Naess (see details in note 15 below). The

SERIES EDITOR'S INTRODUCTION

first of the festschrifts, *In Sceptical Wonder: Inquiries into the Philosophy of Arne Naess on the Occasion of His Seventieth Birthday*, edited by Ingemund Gullvåg and Jon Wetlesen (Oslo: Universitetsforlaget, 1982), contains the most thoroughgoing analyses and critiques of Naess's earlier philosophy that I am aware of, and many of the articles have insightful responses by Naess.

Books

Warwick Fox, *Toward a Transpersonal Ecology: Developing New Foundations for Environmentalism* (Boston and London: Shambhala, 1990). See, especially, chapter 4, "Arne Naess and the Meanings of Deep Ecology."

Ola A. Hegdal and Tore Strand Olsen (illustrator), *Jeg, Arne Naess: Et Tegnet Liv* (Arne Naess: A cartoon story of my life) (Oslo: Kagge Forlag, 2001). A unique and insightful look at Arne's life, based on an idea from Arne's wife, Kit-Fai.

Singh, ed., *Environmental Ethics and the Power of Place: Festschrift to Arne Naess* (Varanasi, India: National Geographical Journal of India, 1994); Nina Witoszek and Andrew Brennan, eds., *Philosophical Dialogues: Arne Naess and the Progress of Ecophilosophy* (Oslo: Centre for Development and the Environment, 1997; Lanham, MD: Roman and Littlefield, 1998); Andrew Light and David Rothenberg, eds., *Arne Naess's Environmental Thought*, special edition of *Inquiry* 39 (June 1996).
16. Arne Naess, *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre*, translated by Alastair Hannay (Chicago: University of Chicago Press, 1968). In the 1970s, philosophy was still influenced by the events of the Second World War. Heidegger's flirtation with National Socialism and the Hitler regime, and his unusual way of expressing himself, made it difficult for him to be considered a great philosopher. Naess's book on four contemporary

SERIES EDITOR'S INTRODUCTION

philosophers was seen as unique because he interpreted in a scholarly and positive way both Heidegger and the fiercely anti-Heideggerian philosopher Rudolph Carnap, a logical empiricist. Carnap, who was forced to flee Nazi Germany, could not fathom how Naess, as an old friend, could present positive discussions of Heidegger and himself in the same book. The other two philosophers included in the book, Wittgenstein and Sartre, also held completely incompatible views of philosophy, but Naess accorded them equally high positive appreciation.

17. For example, works by Naess that are still in print, such as *Ecology, Community, and Lifestyle: Outline of an Ecosophy*, translated and edited by David Rothenberg (Cambridge: The University Press, 1989), and *Life's Philosophy* (2002; see note 2), were not included, for obvious reasons.
18. In "How my philosophy seemed to develop," p. 215, Naess mentions the particularly strong impression, the magnificent expansion of his own "life's frame of reference," made by H. G. Wells's early popularization of the history of life, *Outline of History* (New York: Macmillan, 1920).
19. For detailed discussions of Naess's assessment of logical empiricism, see Arne Naess, "How can the empirical movement be promoted today? A discussion of the empiricism of Otto Neurath and Rudolph Carnap," in *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. Vandormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), pp. 107–55 (in SWAN VIII). (The original German version of Naess's article, "Wie Fördert Man Heute die Empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolph Carnap," was written during 1937–39.) For Naess's experiences attending the Schlick seminar, see Arne Naess, "Logical empiricism and the uniqueness of the Schlick seminar: A personal experience with consequences," in *Scientific Philosophy*, edited by Friedrich Stadler (Dordrecht: Kluwer Academic, 1993), pp. 11–25 (in SWAN VIII).
20. Naess, "How my philosophy seemed to develop," p. 222.

Schilpp (Chicago: Northwestern University Press, 1939), p. 597, as quoted in Wallace I. Matson, *A New History of Philosophy*, vol. 2 (San Diego: Harcourt Brace Jovanovich, 1987), p. 454.
23. Naess, "How my philosophy seemed to develop," p. 223. For more details, see Richard McKeon and Stein Rokkan, eds., *Democracy in a World of Tensions* (Chicago: University of Chicago Press, 1951). Naess, as the scientific leader of the project, was viewed as a UNESCO administrator; he was only credited as

SERIES EDITOR'S INTRODUCTION

- being the author of the questionnaire itself and the summary paper, although he was intimately involved with the project at all levels.
24. Naess went on to perform a reconnaissance of Tirich Mir (25,263 feet) in the Hindu Kush in the summer of 1949. He then led the successful Norwegian first-ascent team in 1950. The expedition, which included botanical and geological assessments of the region, is chronicled by the team members in Naess et al., *Tirich Mir: The Norwegian Himalaya Expedition*, translated by Sölvi and Richard Bateson (London: Hodder and Stoughton, 1952). Naess successfully pursued a second, vastly more technical expedition to Tirich Mir in 1964. His "The south wall of Tirich Mir East," *Himalayan Journal* 26 (1965): 97–106, discusses this expedition and includes interesting commentary on expedition philosophy and climbing ethics. The article appears in SWAN X, along with other papers on Naess's relationship to mountains and views on mountaineering.

ogy approach to ecophilosophy," the "deep ecology movement," and Naess's "Ecosophy T" (a particular deep ecological total view), see Harold Glasser, "Deep ecology," in *International Encyclopedia of Social and Behavioral Sciences*, edited by Neil J. Smelser and Paul B. Bates (Oxford: Pergamon, 2001), pp. 4041–45. For a detailed discussion of deep ecology as an ecophilosophical approach with special attention to its policy implications and a discussion of deep ecology's relationship to Naess's earlier philosophical work, see Harold Glasser, "Naess's deep ecology approach and environmental policy," *Inquiry* 39 (1996): 157–87 (reprinted in Witoszek and Brennan's *Philosophical Dialogues*).

31. For anthologies on the deep ecology movement, which include articles by Naess and other deep ecology supporters, see George Sessions, ed., *Deep Ecology for the Twenty-First Century* (Boston: Shambhala, 1995), and Alan Drengson and Yuichi Inoue, eds., *The Deep Ecology Movement: An Introductory Anthology* (Berkeley, CA: North Atlantic Books, 1995).
32. Naess rarely responds directly and definitively to these criticisms—this is not his nature. Siri Naess, however, made an interesting effort to explore the potential of using Naess's Ecosophy T as an inspiration for a feminist normative system in her "Self-realization," in *In Sceptical Wonder*, pp. 270–81. She concluded that while Ecosophy T and her System F have much in common, Ecosophy T goes further by extending to all living beings its concern for activeness and creativity in relation to problems, egalitarianism, and support of the suppressed and exploited.

Author's Introduction to the Series

At ninety-two it is a great honor to be still alive and to witness the publication of my selected works in English. Few philosophers have their work published in a series, fewer still receive this honor before they die. When I was originally approached with the idea of publishing my complete works, I was overwhelmed and overjoyed, but added that not all my books and articles were important enough to merit such an honor. Selected works? Yes, and I am extremely grateful for this initiative and the final result, which presents a representative selection of my work from the earliest to the most recent. [*The Selected Works of Arne Naess* are hereafter referred to as SWAN.]

My interest in philosophy began with Spinoza's *Ethics*, which as a seventeen-year-old I was fortunate to read in Latin. I appreciated Spinoza's grand vision and trusted him implicitly as a person. I accepted that human beings could, and should, have a general outlook with the grandeur of Spinoza's, but I recognized that our individual views on this grand scale will not be identical. Through the years I have realized that there is a splendid variety of interpretations of Spinoza (SWAN VI and IX). His texts are exceptionally rich. As the years have gone on, I have focused on how he leads us to realize we can increase our freedom and sense of connection with the world through strengthening and intensifying our *positive* emotions. For example, loving and caring for our place and others leads to an expansive sense of being part of a much larger world. Emphasizing hatred and anger, on the other hand, makes us feel smaller and isolated from the world. Spinoza, as I interpret him, would express this by saying that "We are as large as our love." Increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow.

Before I left gymnasium [the end of secondary education] the headmaster asked me, "What do you intend to be?" My immediate answer was "A philosopher." In fact, I had already conceived of myself as one. I viewed the

AUTHOR'S INTRODUCTION TO THE SERIES

writings of many contemporary philosophers that I was familiar with, however, as vague and airy and certainly not as inspiring as Spinoza.

My doctoral thesis in philosophy of science was an effort to remind us that in science the content of a theory is not independent of research behavior—the activities of observing, confirming, disconfirming, and so on, and that these are set within a deep context of place, history, and culture. Later, as a postdoctoral researcher at the University of California at Berkeley, I studied the behavior of experimental psychologists doing animal research.

In 1934 and 1935 I studied in Vienna and while there became a member of the famous Schlick seminar, the main discussion group of the Vienna Circle. Their quest for clarity and cordial cooperation in pursuit of knowledge led me to appreciate that “What do I mean?” is an open question. I concluded that we never intend to express anything extremely definite, even in mathematics or symbolic logic. I saw the importance of using empirical methods to find out how we actually use certain expressions and sentences. I developed and applied a wide variety of such methods, which became part of the core for the empirical semantics that runs through my work. I continued to do this type of research into the 1990s, my last project being one in which I questioned experts and policy makers about their ideas of values intrinsic to the natural world (in SWAN X).

In one of my earlier studies, I reviewed about 700 articles from philosophers concerning their use of the word *truth*. For the most part, I found these unconvincing and soon started on empirical studies of the use of *truth* among ordinary nonprofessional people and schoolchildren (in SWAN VIII). Many philosophers seemed to assume that ordinary people hold very naive views about these deep matters. I found through research that, on the contrary, the views articulated by these “ordinary” people were every bit as sophisticated as those held by professional philosophers. This reinforced my conviction that, generally, we greatly underestimate ourselves. Much academic philosophy was narrowly focused and abstract. Philosophers who elicited interest in wide-ranging issues of practical and global importance, such as nonviolence and social justice, have in my lifetime said things that were considered creative, but often too far out. In spite of consistent proclamations that science neither would nor could take over all the problems discussed by philosophers, I tried to argue in ways that reminded readers of science done as open inquiry, and I tried to emphasize that it is occasionally

AUTHOR'S INTRODUCTION TO THE SERIES

necessary to perform empirical research to illuminate or support a philosophical viewpoint.

My empirical and historical research led me to realize that there are no certainties and that there is a great diversity in our spontaneous experience as well as endless ways to describe and appreciate the complexities and values of the world. Thus, I realized that I am one of those lifetime seekers that the ancient Greeks called a *zetetic* (see SWAN II and VIII). From my research on scepticism and the foundations of science and logic, it became clear to me that pluralism (every event has many descriptions and possible outcomes), possibilism (anything can happen), and a healthy scepticism (always seeking the truth but never claiming it) make up the most consistent approach to respecting the perspectives and experiences of others, human and nonhuman.

From my empirical studies of semantics, and from my knowledge of several languages, I came to appreciate the complexity of communication. Being committed to Gandhian nonviolent communication, I saw the importance of avoiding dogmatism and fanaticism. One of the most important discoveries coming from this research, leading to the publication of my major book, *Interpretation and Preciseness* (SWAN I), was the insight that we cannot avoid values in any field of endeavor or research. There are no value-free inquiries or theories. Even if we refuse to express our values, this is itself an expression and choice of values. We must, therefore, be clear about our value choices and try to make them explicit. The choices we make, as Spinoza pointed out, shape the quality of our lives, and values emphasizing positive emotions or feelings are expansive and lead to our growth. We must become ever more aware of our choices and the values involved. Even pure logic assumes certain norms. Empirical research can shed light on these matters. My colleagues in philosophy often found my empirical work perplexing. I, in turn, grew to underrate the necessity of visiting great centers of philosophy, as I preferred to be close to or in the mountains.

When I visited the United States, it was mostly to climb in the mountains or walk and camp in the desert. On one fortunate visit, I dropped in at the graduate students' discussion room at Harvard. Speaking with students who were writing their doctoral theses in philosophy, I understood that my knowledge of contemporary philosophy, and of recent important contributions in its various fields, was narrowly limited to special themes of lively personal interest. Even in later years, the tendency to take personal inclina-

AUTHOR'S INTRODUCTION TO THE SERIES

tion very seriously colored my contribution to the philosophical literature. As can be seen, though, from the titles in these *Selected Works*, my strongly felt interests span a rich variety of fields, philosophical traditions, and movements.

Since childhood I have experienced an intense joy in being together with animals and plants and in contemplating the immense evolutionary development of life on earth over millions of years. From an early age I also developed an intense love for mountains and for being in them. Much of my creative philosophical work was done at Tvergastein, my mountain hut in Norway (see SWAN X). My devotion to outdoor life is in the Norwegian tradition called *friluftsliv* (literally, free-air-life). In many respects, I approached philosophical and cross-cultural studies as if I were a field ecologist or naturalist. It was against this background that my work from the 1960s onward focused with close attention on cultural diversity, biodiversity, sustainability, and the deep ecology movement.

My work since the Second World War has been increasingly within movements such as those furthering social justice, peace, and ecological responsibility. During the war, I engaged in anti-Nazi activism, and from that time also in promilitant Gandhianism, a nonviolence that is not pacifist in the usual sense but insists that if it is a bloody fight for justice against injustice, we seek "the center of the conflict" and, if necessary, cooperate with people who use arms. During the Cold War, I participated in the "third side," against both communism and extreme anticommunism, for example, as the scientific leader of a UNESCO project bringing Marxist and anti-Marxist politicians and political science researchers together in an unbiased discussion of the essence of democracy and freedom. Some of the relevant publications are included in SWAN IX.

The broad spectrum of books and articles included in the *Selected Works* represents, in many ways, a chronicle of my passions and influences. The *Selected Works* record, albeit in an inevitably fragmentary way, one possible expression of these. My dream and hope is that some readers will be inspired by their sheer variety, and that young philosophers will be encouraged to let strong personal motivations steer their studies.

Working habits vary. Some people write an article and go on to the next without looking back on the old one; others come back from time to time, radically revising and changing the old one. The latter is my way of working. Lecturing in many places about these subjects, I have found it

AUTHOR'S INTRODUCTION TO THE SERIES

natural to revise the old manuscripts until sometimes very little is left of the original. Therefore, I have always viewed my writing as preliminary; a year, five years, ten years after publication of the first editions I have itched to revise, *thoroughly* revise them. When my first book was printed in 1936, I went to watch the hulking presses printing out one page at a time. I was terrified, thinking of mistakes or some awkward sentences being duplicated again and again.

When I was offered the opportunity to have a selected-works series published, I immediately thought I would like to review all my work and ask how, from today's perspective, I might answer the difficult questions I had earlier attempted to probe. Such a task would have been a particularly difficult proposition, because although many of my books and articles contain new ideas, the ideas are often not developed as well as I might have hoped. But alas, I am saved—at my age there is not time for me to accomplish such a comprehensive reevaluation of my work; I do not even have the capacity to do it now in any case.

Who could contemplate undertaking a publishing project of such ambitious proportions? Douglas Tompkins, mountaineer, entrepreneur, protector of wilderness in Chile and Argentina, and creator of the Foundation for Deep Ecology, is such a person. "Miracle Doug," as I call him, likes the idea that the deep ecology slogans and the deep ecology approach were introduced by a philosopher. I am grateful to him for his firm conviction, inspiration, and great generosity. My gratitude, however, extends well beyond my thanks to Doug, to others who have supported and championed this project.

Quincey Imhoff, when executive director of the Foundation for Deep Ecology, supported SWAN with generous grants and other contributions. SWAN has also benefited from faithful assistance and cooperation in the preparation and editing of the manuscripts. The late Professor Ingemund Gullvåg prepared the initial translation of *Which World Is the Real One?* (SWAN III). Professor Alastair Hannay translated the first edition of *Communication and Argument* (SWAN VII) and offered invaluable suggestions for improving the readability of the first editions of *Scepticism* (SWAN II), *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), and *Gandhi and Group Conflict* (SWAN V).

Most of all, however, I am grateful to Harold Glasser, the series editor, and his assistant, Kim Zetter, who oversaw all aspects of the project from design to production. Glasser's unique combination of intellectual tenacity,

AUTHOR'S INTRODUCTION TO THE SERIES

attention to detail, mastery of my work, and cooperative spirit made him a natural to take on the monumental task of selecting and editing my works. Glasser not only labored to improve the English and clarity of each manuscript, but his keen ability to ferret out countless technical and pedagogical errors has resulted in substantial new editions of volumes II–VII that are both far more comprehensible and accessible than the originals. I thank him for his valiant work on this project, both during his stay in Norway as a visiting Fulbright professor, where we collaborated on a strategy for revising the previously existing material, and in the subsequent years it has taken to complete the project.

From the beginning of the SWAN Project in 1994, Alan Drengson has encouraged and helped to move this work forward in numerous ways. Especially in the last crucial stages of completing volumes I, VIII, IX, and X, his help and editorial oversight have been invaluable. Thanks for his devotion, good humor, and positive enthusiasm. Thanks to both Drengson and Tim Quick for their extensive bibliographic research. Thanks to Bill Devall for his support and encouragement and especially his help on the completion of volume X, *Deep Ecology of Wisdom*. Thanks to Anne Collins for her outstanding work as the copyeditor of the SWAN volumes. Thanks to George Sessions for his support and encouragement.

Last, but certainly not least, immeasurable thanks go to my wife, Kit-Fai Naess, who has worked beside me throughout the years to provide invaluable assistance, encouragement, and inspiration.

Arne Naess

2004

Author's Preface to This Edition

There are different philosophical traditions within higher education. When I became the full professor of philosophy at the University of Oslo in 1939, university regulations required teaching logic to all entering students. In my course I tried out propositional calculus with ample application to everyday problems. The students found the course amusing. I soon developed a course using a textbook that in translation is entitled *Communication and Argument*. About a hundred thousand students went through this course from 1941 to 1970, in small groups, ideally of fifteen students. Sometimes the groups degenerated into masses of more than twenty.

The aim of this highly practical course was to change nearly every university student's attitude toward communication and argument. The students came to feel that, strictly speaking, they never meant anything *very* definite when they were arguing, or when thinking in general. In everyday life it is unnecessary and even harmful to search for maximum preciseness. At the university level every student should know what it takes to be fairly precise. Sometimes a high level of *definiteness of intention* is required for some purposes.

Some colleagues and parents were highly critical of this course. One year, when a new university president was being elected, a professor announced that the election was a vote for or against my logic course.

When I read the text today, it is easy to understand the course's hidden dynamite: the teachers and students were supposed to use examples from the political, social, or ethical debates raging in the newspapers, or among faculty and students. The more emotional the subject was, the better. Each student was supposed to be confronted with his or her own confusions. This can be threatening to established thinking.

When asked whether he thought he meant something completely un-

AUTHOR'S PREFACE TO THIS EDITION

ambiguous and precise when he wrote or said that he had *proved* something, the world-famous mathematical logician Thoralf Skolem, after some hesitation, and to my disappointment, answered yes. As I understand it, there is uncertainty about what *exactly* means in the abysmal debate on the fundamentals of proof theory.

The English translation of *Communication and Argument* is somewhat watered down. The original Norwegian book—complete with exercises—is the only textbook that I regret was not used more extensively, say, by a thousand times as many students, that is, a hundred million.

The last chapter is an application of the ethics of nonviolence in discussions and controversies. The title “Effective Discussion” is somewhat misleading. It was only under pressure that I did not call the rules Gandhian. At every moment we have to treat an opponent in a debate as an inviolable, sovereign person. Whatever his or her behavior, misquotations, insinuations, attitude of contempt, one should remain unruffled and not deviate from the theme of the discussion. Against this it was objected that debates must be amusing or dramatic because, otherwise, very few are willing, or even able, to concentrate for more than a few moments. Actually, at public meetings the students following these rules did not win debates. They tended to be serene and dull, but that is *not* required. One can make jokes and do amusing things, but not in a way that might mislead and thereby influence the argumentation. This is very difficult! Training is, of course, necessary. They did not get that in my course. On at least one occasion the result was deplorable: A famous poet and actor attacked science in a most witty and brilliant way. The thousand listeners, all students who had taken the course, enjoyed the performance, but they felt and were helpless in the ensuing debate. Therefore, the actor “won.”

In the West there is talk about “the intelligentsia” as a special layer of a modern society. Through hundreds of years, the French were seen as leaders of intelligent spiritual communication. When I had the opportunity to *influence* all newly enrolled Norwegian university students through the required logic course, I decided to give a course in the *practice* of communication. It was given at a sufficiently high level to match the ideals of a minority, and so I focused on communication in social and spiritual *conflicts*. The text was meant to assist the students in discovering good examples of communication in situations of conflict. In conflicts it is normal to depict opponents as stupid and satanic, using all kinds of tricks. However, there

AUTHOR'S PREFACE TO THIS EDITION

are also misunderstandings due to vagueness, ambiguity, use of slogans as if they were arguments, and so on. This book (SWAN VII) outlines practical standards of goals for Gandhian communication. A new chapter outlines some topics of the hermeneutic movement.

The empirical semantics in this book is used in everything I write, and especially in articles on the deep ecology movement. This explains my good relations with theorists of social ecology and Third World authors, who feel that the West pressures them on ecological policies. North/South debates need the ethics of communication and argument described herein.

The *Times Literary Supplement* said of *Communication and Argument*: "Its main purpose is well defined: to teach people in a democratic society to think clearly, and above all, responsibly. Its six chapters are concerned with interpretation, precision and definition, analytic and synthetic sentences, agreement and disagreement, *pro-et-contra* and *pro-aut-contra* arguments and the factors contributing to effective discussion. Probably no philosopher or sociologist now living could peruse this simple manual without learning something from it."

Author's Foreword to the First Edition

Language is used in many different ways and for many different purposes. It may even be “used” without any purpose at all, as when we exclaim unintentionally or become delirious. Generally, people use language to communicate, but by no means always: they also sing for their enjoyment, utter incantations for rain, indulge in polite chatter, and stall for time. Even when language serves purposes of communication, it can, at the same time, have an expressive and evocative function. Nevertheless, the most common uses of language are those in which it serves a straightforward, practical function of communication: we ask for or give information, explain, advise, warn, argue, agree, promise, persuade, preach, or pray. In all such uses, its main feature is something that can be found in any function of language to some degree: a so-called cognitive content. In this book, the primary concern is with those uses of language in which the cognitive content of an expression takes the form of an assertion, that is, when something or another is stated to be the case. The kind of communication in which these uses are central is sometimes called cognitive discourse.

The most obvious case of cognitive discourse is a straightforward assertion about something we can or could perceive to be the case. Less obvious, but clearly also belonging to cognitive discourse, are instances when people engage in abstract and theoretical speculations and their views are aired for public discussion and argument. In fact, whenever we say something and are ready to say something else in support of it, we speak in the “cognitive vein.” Thus, when John Stuart Mill claims that happiness is desirable because—and for him it is a *reason*—men desire only happiness, his statement belongs to cognitive discourse.

The concern here is not with knowledge, truth, and validity as such—it is not with how we should analyze statements that someone knows (e.g., that gooseberries grow on bushes, that two and two are four, or that happi-

AUTHOR'S FOREWORD TO THE FIRST EDITION

ness is desirable), nor with what is meant by saying that such things are true or false. The concern is rather with the more immediate problem of identifying what people—including ourselves—mean when they say things that are in principle open to argument. The problem is a practical one of interpretation, dealing with difficulties arising from the fact that one word sequence can have more than one meaning and that a number of different word sequences can have the same meaning.

It may be helpful to note in passing that the question of interpretation does not arise only in regard to the cognitive content of expressions, as I have roughly defined it above; whenever words are uttered, another question of how to interpret what we hear may arise. When someone swears, is this a genuine reaction or is it only an affectation, or perhaps a rehearsal of some kind? In any use of language, there can arise the question of how (or even whether) a given utterance is meant; but this question of “how” differs from the question of “what.” When we ask ourselves, “What does he mean?,” we are not wondering how we are to treat what he says but rather what precisely it is that he is saying, regardless of whether he says it sincerely, insincerely, or even unconsciously.

I

Interpretation

Grasping What Others Mean

In the normal course of daily life, and at least within our own group, we make ourselves more or less understood. This is evident from the way people behave and is an essential part of the normality of daily life. Even if the people we talk to have not shared some of our own experiences, they can understand us when we describe them. A student who exclaims “I can’t face the thought of the exams” can be quite sure that at least his friends will grasp fairly well what he means, whether or not they, too, feel — or have ever felt — the way he does about taking examinations.

That serious misunderstandings are usually avoided in everyday life is because language is rather like a set of games, which we come to learn in common with other players. However, it is also because fairly stable patterns of events constantly repeat themselves and so become recognizable occasions for using certain expressions. Since John Doe regularly comes on the eight o’clock train in the evening, when one of his friends says to another that he’ll be here shortly after eight o’clock, there’s little chance that the latter will be misled into thinking that John will arrive shortly after eight in the morning. In a whole host of similar cases in everyday life, strict accuracy is not required — but, of course, sometimes it is. Because we can so often get along without it, when exactness *is* called for, we are often too little prepared for it, and this is when misunderstandings often arise.

That the meaning of an expression is fairly clearly delimited on one occasion does not prevent that same expression from expressing something quite different in another context. An expression’s meaning always depends in part on its relationship to other expressions and events, in other words, on its context. When considering an expression’s context, we must include its *linguistic* context — the area or level of discourse, written or spoken — as

INTERPRETATION

well as its *nonlinguistic* context—the kind of situation in which it is used. A textbook, for example, is designed for a special context in that it has a certain standard of mental development and level of knowledge in view. The author knows his readers and tailors his expressions to their requirements. Outside the limits of this audience, his words must be expected to give rise to more frequent and more serious misunderstandings of his meaning.

Of course, the fact that the same words uttered in one context can have a different meaning in another does not itself generate misunderstanding. When this occurs in the form of simple ambiguity—a typical source of comic-strip humor—misunderstanding usually presents little practical difficulty. For example, someone says, “Stanislavsky made some interesting comments on the stage.” On being asked “What about?,” he replies, “I told you—about the stage,” and this eliminates any confusion.

Unfortunately, ambiguities and difficulties of interpretation that have considerable theoretical and practical consequences can also occur. For example, ambiguities may arise because of subtle modifications in a situation—perhaps a sudden tension when someone enters the room, plainly felt but hard to describe—or difficulties may arise from attributing distinct meanings to the utterances of another person when he has nothing so distinct in mind. Similar problems arise in one’s own utterances, due perhaps to an inability to think about one thing consistently, or to think clearly enough in a situation that requires unusual sensibility or intelligence. One can think of many such cases of significant ambiguity.

When arguing logically, whether in open debate or in presenting a scientific thesis, we assume that our words have a well-delimited meaning and that any latent ambiguities are easily recognizable and harmless. Any application of logic can therefore be said to presuppose a *theory of interpretation*. The type of word sequences in which logic plays a special role are of the form in which one or more sentences can express a thought or an opinion. Such word sequences express something that can be true or false. Since we sometimes convey thoughts by expressions that are not grammatically proper sentences, it would be better to make use of the wider term *expression*. Instances of expressions include “The Earth is round,” “The Earth is flat,” “He who laughs last laughs longest,” and occasionally even single words. (When one man looks another straight in the face and says “Idiot!,” he usually means “You are an idiot!”) We will use the term *statements* to refer to the *ideas* or *thought-content* an expression expresses. “The Earth is flat,”

“La terre est plat,” and “Jorden er flat” are three different expressions that express the same statement, the statement that the Earth is flat.

The question of what a statement “really is” leads to difficult philosophical problems that this introductory work will not consider. All that is needed here is to grasp the importance of the distinction between a word sequence such as “The Earth is flat” and what this word sequence expresses in terms of thought-content for speakers of English. That there is a distinction is obvious from the fact that different expressions can express the same statement and that the same expression can — according to context — express different statements.

A sentence that (sometimes or always) expresses a statement can be said to *function* as an assertion. Of course, the same expression can also have other, accompanying functions. The sentence “An anonymous phone call says there is a timebomb under this house set to go off at four o’clock” not only asserts something but also invites an immediate response. At one minute before four o’clock, it might be appropriate just to shout “Bomb!” Yet even this patently signal-oriented expression has an asserting function, although one that is less clearly defined. In fact, the signal effect that a word has depends on its functioning in some part as an assertion. Whether a signal function, an assertion function, or any other kind of function is operative depends on the listener’s grasp of the situation in which the expression occurs. An actor who discovers a fire behind the scenes of a stage play may shout “Fire!,” but if he is a comedian, the audience may only laugh and clap, the more so the greater his expressions of anxiety and despair. They do not grasp the intended function of the word *fire*.

Expressions are made from words or collections of words; this is not so for statements. A translation of a proverb from one language into another need not employ the same number or even the same grammatical kind of words as the original in order for the content — the idea expressed — to be the same. Although our purposes in this book do not require us to go further into this point, it is important for the reader to be aware that the connection between an idea and the words used to express that idea is a complicated one and less obvious than often assumed. For example, the expression “The Earth is round” is English, but the statement our English speaker conveys with it is not restricted to English or to any other language.

Besides the difficult and not altogether clear distinction between a statement and the words or phrases used to express it, we have to distinguish be-

INTERPRETATION

Figure 1. Relationships among expressions (“A”), statements (‘C’), and states of affairs (B).

tween a statement and the state of affairs it refers to or its “reference.” “The Earth is flat” expresses a statement that most of us deny. The proposition, we would say, is false. The state of affairs that the expression claims to exist *does not exist*; the facts contradict what is alleged, and the expression therefore fails to correspond with reality. The essential difference among an expression, a statement, and a state of affairs can be described briefly. We make and try to convey *statements* by means of *expressions*. (A recurring question throughout this book will be how to form expressions that best convey well-defined thoughts.) A statement can be true or false, tenable or untenable, valid or invalid, depending on the state of affairs it refers to. The threefold distinction among expression, statement, and state of affairs can be represented in the triangle above that shows the relationships among “A,” B, and ‘C’ entities (figure 1).

Expressions, which are created with words, terms, or sentences, are referred to as “A” entities. They express something, namely ‘C’ entities, which refer to statements—thought-contents, ideas, or concepts. While words and terms *sometimes* express statements, expressions—in our use of the term—*always* express statements. The particular states of affairs that are referred to or suggested by expressions are B entities.

This book focuses on the distinction between “A” entities and ‘C’ entities; the main concern is to explore this distinction and develop a systematic terminology to account for it. The distinction between double and single quotation marks helps to distinguish expressions from the ideas of

concepts they refer to. The distinction itself is of great practical importance in all areas of communication and is essential to a grasp of semantics. To understand what people say or write, we must identify certain 'C' entities, but we can only do so on the basis of the expressions provided, that is, by means of the "A" entities made available to us. Let us now consider some implications of this.

Suppose you read an excerpt from an obituary that says, "Just recently he suffered much. He was chairman of the Philosophical Association. . . ." Taken separately, the two expressions have nothing particularly odd about them, but combined they suggest, curiously, that the second statement is intended to provide a causal explanation for the first statement. We tend to feel drawn toward interpreting the excerpt incorrectly as, "Just recently he has suffered much; you see, he was chairman. . . ." But usually when we read an expression in conjunction with other expressions, the tendency is not, as here, in the direction of misunderstanding. On the contrary, because such a conjunction of expressions fills in some of the context, it should lead to an increase of explicitness and hence a decrease in the risk of misinterpreting what we read or hear. If we are given the context in which an expression occurs, the expression acquires a more sharply delimited meaning than if we hear it in a complete contextual vacuum. We are much more liable to misunderstand *isolated* sentences, and this is naturally a contributing cause of considerable irrelevant discussion. However, unless each constituent expression of any conjunction of expressions has a sufficiently clear sense of its own, it is difficult to form or convey with such a word sequence any reasonably complex and definite meaning. Therefore, each sentence must on its own satisfy certain requirements of preciseness and unambiguity. After all, we have to read sentences one at a time; an author cannot expect us to wait until we have read the last page of his book before we understand the sentences on the first page. Each expression contributes to the whole of which it is a part and can do so only insofar as it is itself capable of having a clear sense. In what follows, we will be concerned mainly with the interpretation of isolated expressions.

The development of science and technology has made a number of new demands on our linguistic usage. Scientists spend a good deal of their time polishing the language that is their tool, both for precise thinking and for effective communication of their results. Thus, when people talk about

INTERPRETATION

“correct usage,” we must remember that, although the ordinary rules are fitted to everyday requirements for preciseness, they are not adequate when it comes to determining the precise meanings of expressions resulting from prolonged and careful reflection. Besides, growth in understanding and articulateness is linked with the ability of our expressions to acquire new meanings, to bring themselves under new rules.

Linguistic usage, then, must vary in ways that we can hardly expect even experts in usage to keep up with. Different people mean different things by the same expression or the same thing by different expressions, without doing any violence to the English language. Even such a simple sentence as “Mount Whitecap is higher than Mount Baretop” could have at least two distinct meanings: that expressed by “Mount Whitecap’s highest fixed point is higher than Mount Baretop” or that expressed by “Mount Whitecap’s highest point, snowcap, or rock is higher than Mount Baretop’s.” An English speaker, on hearing the expression “Mount Whitecap is higher than Mount Baretop,” might take it to mean either of these — or perhaps neither of them but some third possibility entirely. Even more likely, he may not have considered the possibility of a distinction between the two assertions, not having considered the subtle issues of measuring heights. In such a case, we certainly cannot determine the meaning by appealing to the correct use of the sentence concerned. Linguistic expressions, whether sentences, phrases, or words, are far too accommodating to permit any exact determinations of their “correct” usage. The openness in the rules mentioned above allows words and sentences to have perpetual variability in meaning, something that permits them to be both vehicles for advances in understanding and sensibility, and cloaks for ambivalence and ignorance. If we were to say that the use of correct English presupposed crystal-clear thinking, then we must make do with incorrect English, adopt some other language, or else give up speaking altogether.

The theory of interpretation is concerned first and foremost with clarifying how the same word sequence can express different meanings and how one and the same meaning can be expressed by different sequences of words. It is also concerned with drawing consequences from these clarifications and with evolving a suitable terminology for effective and precise discussion of these issues. As such, therefore, it is not directly concerned with whether an expression is used correctly or validly. Indirectly, however, the

truth or falsity of an assertion can play a significant part in determining interpretations. If someone says “I saw Eternity the other night,” and I know he is neither mad nor a mystic, I would immediately reject one literal interpretation of the expression. Instead of assuming that someone is claiming he saw Eternity, as opposed to Temporality, I would probably assume that he is reciting the first line of Vaughan’s poem or else would guess that “Eternity” is the title of a film. My own assumption as to what can be reasonably asserted to be true and the range of possible interpretations that I can envisage determine in part what I take to be the reasonable choice of interpretation.

When we suspect that an expression we use might not be understood as we intend it to be, we often resort to alternative expressions that mean the same or roughly the same, hoping that with these we can help the listener identify our meaning. Expressions that convey the same statement will be called “equivalent expressions.”

If we want to describe something or present an argument, our expressions must be able to convey the relevant cognitive content. But this cognitive content can be conveyed, more or less effectively, by different expressions that, in a wider sense, cannot be said to have the same meaning. Thus, we must distinguish *cognitive* from other kinds of equivalence. An extreme case illustrates the distinction. When Shakespeare’s Coriolanus addresses his mother as “honored mold, wherein this trunk was framed,” the expression “honored mold” could conceivably have meant for him what most of us mean by the more conventional and handier “dear Mother.” That is, insofar as both expressions can be intended to mean the same, or to perform the same role, we could say that they *can* have the same cognitive import. But clearly, in a wider sense of meaning, they would not strictly mean the same. The former version, apart from being at once more vivid and formal, has a broader and more elaborate conceptual content. In a way, it means more than is meant by a person using it to mean the same as “dear Mother,” and it conveys this double meaning whether or not the author has this wider sense in mind. When we speak of cognitive equivalence, therefore, as opposed to a wider or *total* equivalence between expressions, we mean, roughly, that there is some central significance that expressions share and that, at least in some contexts, makes them interchangeable regardless of differences in suggestiveness, style, or sound.

INTERPRETATION

When dealing with expressions, I will speak generally of *statement equivalence* (or nonequivalence) as opposed to equivalence (or nonequivalence) of *cognitive meaning*. The former is a special case of the latter, since cognitive content appears in forms other than that of assertion. In what follows, “equivalence” means the same as “statement equivalence.”

If we are called on to commit ourselves to the truth or falsity of an expression and we are not clear as to what the expression means, there are a number of steps we can take. Perhaps the best is to evaluate every one of the interpretations we are able to ascribe to the expression in the given context. To do this, we must interpret the original expression in all the different ways in which it could plausibly be rendered more precisely. I refer to this process of postulating more precise renderings as “precization.” Some precizations of the original may be tenable, others not. It is thus especially important to be able to distinguish those interpretations we would agree with from those we would disagree with; otherwise we will never be sure whether agreement or disagreement exists, since to know this we must already know what it is we agreed or disagreed on.

In most cases, however, we have neither time nor opportunity to engage in this process of listing all the different interpretations. In such cases, we can resort to the expedient of qualifying our agreement or disagreement by stating how we interpret the expression in question. An example of such a qualification follows: “If, when he says ‘Routine makes one stupid,’ he is referring to the tendency of routine to make most of one’s actions automatic, then I agree.” This procedure saves time, but leaves a certain amount to individual knowledge or intuition if we are to be reasonably sure the interpretation we assess is also the speaker’s.

A theory of interpretation has to account for our ordinary ideas of exactness, accuracy, and preciseness. If it does not, it is hopeless to try to put the theory into practice. The theory must therefore establish its explanatory concepts, first giving definite meanings to expressions such as “interpretation,” “precization,” and “real disagreement.” In everyday language, these expressions have no clearly delimited meanings, but for the purposes of my theory, we must give them technical meanings. These, of course, will correspond only to a certain extent to the ways in which the expressions are used ordinarily. Since a grasp of the technical meanings of these expressions is essential to an understanding of what follows, we shall pay special attention to our terminology in the next three sections.

Equivalence Between Expressions

Many differences between expressions have little or nothing to do with the cognitive content the expressions may share. The words *automobile* and *car*, for example, express no cognitive distinction, although the words themselves are quite different. There are times, however, when it can be difficult to sift out differences that are purely verbal and not cognitive—as in the case of pure synonyms—from those that are cognitive as well as verbal. Furthermore, when there are cognitive differences, it is often difficult to specify the extent to which the cognitive contents of the given expressions differ.

Throughout this book, *T* and *U* will symbolize expressions, *P* a person or group of persons, and *S* a situation (or a situation type, i.e., a determinate pattern of events or state of affairs, including the linguistic and nonlinguistic context, which are not necessarily restricted to one occasion) for which *T* and *U* can be linguistically appropriate expressions.

Let us consider the ways in which just two expressions can be equivalent (statement equivalent). The following six cases of equivalence between *T* and *U* can be distinguished:

1. Whatever the situation, *T* and *U* express the same for anyone competent in the language.
2. For at least one situation, *T* and *U* express the same for everyone.
3. For each person, *T* and *U* express the same for at least one situation.
4. For some people, *T* and *U* express the same for all situations.
5. For each situation, *T* and *U* express the same for at least one person.
6. For at least one situation, *T* and *U* express the same for some people.

These six cases represent ways or degrees in which *T* and *U* can be regarded as expressing the same statement (being equivalent expressions). The logical relationships among 1 through 6 can be depicted in a diagram with arrows pointing to the respective logical consequences of each case (figure 2). The seventh case—in which *T* and *U* do not express the same thing for any situation—occurs only when there is no equivalence. A helpful exercise at this point is to try to state the six cases of nonequivalence of expressions corresponding to 1 through 6.

Here are some examples of the six ways in which expressions *can* be equivalent. The example “Mount Whitecap is higher than Mount Baretop”

INTERPRETATION

Figure 2. Logical relationship of the six forms of equivalence for expressions T and U .

(T) and “Mount Baretop is lower than Mount Whitecap” (U) can provide us with an instance of case 1. For all speakers of English, these two expressions probably amount to the same statement—but only probably, because whether or not they do can be decided only by a necessarily incomplete empirical investigation. Another significant factor here is that the way people use the word *same* is itself by no means clear and unambiguous. For example, do we say that T and U here express the same meaning, even though “is higher than” occurs in T and “is lower than” in U ? Instead, might we argue that they are different ways of saying the same thing, or perhaps that they express different but equivalent *statements*? Further reflections on this issue are left to the reader.

An instance of case 2, in which for at least one situation T and U represent equivalent expressions for everyone, can be provided by the pair of expressions “Baldy is higher than Snowy” and “Mount Baretop is higher than Mount Whitecap.” In some contexts, these expressions may mean the same: for example, in a discussion between two climbers who know the peaks in question and are familiar with the shorter names for them. But unless one is familiar with these “nicknames,” one will merely be baffled and probably assume that they express two quite different statements.

An example of case 4, in which two expressions express the same (whatever the situation) but not for everyone, might be: “He is twenty years old” and “He has reached his twentieth birthday, but not his twenty-first” (some

might assess a person's age by his nearest birthday). Examples of case 6, in which two expressions are equivalent for only some people and for at least one situation, are easy to find; for instance, "The election will be next month" and "The election of the chairperson will be next month."

These six cases of equivalence provide a basis for precizing and explicating the following forms of expression: "by *T* is meant *U*," "in English, *T* means the same as *U*," "*T* or, in other words, *U*," and "strictly speaking, *T* does not mean the same as *U*." Not infrequently one comes across rash and imprecise pronouncements about which expressions do and do not mean the same thing. Unfortunately, this is often the case in literary discussions in which preciseness should be of the essence. This is exactly where one should ask the following questions: The same total meaning or the same cognitive meaning? The same for whom? In what situation? Correct according to whose standards?

Usually we find that the relatively less determinate notion of 'total meaning equivalence' serves only special interests and therefore concerns only some people in some situations. We should bear in mind how often we would replace unreflectively "When one says *T*, one means *U*" with "When I say *T*, I mean *U*." We presume all too commonly and rashly that what applies in our own case, or in that of some limited group, is also true generally.

When we say that two expressions, *T* and *U*, are equivalent for someone, it is not necessary to imply that some person has actually used *T* and *U*; it is sufficient that *T* and *U* would be shown to be equivalent if and when the occasion arose for that person's use of these expressions. If we have yet to hear him using them, we can still make reasonable inferences from his language habits and other factors about what his linguistic future might show us.

However, there is more involved here than merely asking a person, or ourselves, whether two given expressions are equivalent for that person or for us. What we need is a precise terminology and also an ability to compare the expressions from all possible angles. Without such instruments and techniques, the answers we give will tend to confuse the issue rather than clarify it. Consider, for example, the expressions "I ask of myself only what I ask of others" and "I ask of others only what I ask of myself." Can you say straight off, or conclusively, that they mean or do not mean the same to you?

When Are Expressions Equivalent?

We require suitable aids to improve our ability to be clear about what we want to express by some word sequence. Help is also needed in our search for a better way to express what we want to say. Some assistance may be provided by the criterion of *nonequivalence*, which is introduced in this section.

We can think of a person *P* who feels no difficulties in understanding *T* and *U* and for whom, so far, nothing has caused him to doubt what content they express. Nevertheless, the question of nonequivalence can always arise for *P* himself or for another person *Q* who wants to know exactly how *P* interprets *T* and *U*. Do these expressions, or do they not, express the same thought for *P* as he understands them in a specific situation *S*? Suppose we suspect they do. If *P* takes both what *T* expresses and what *U* expresses (for him in *S*) to be untenable, or takes both to be tenable, we may think this shows that *T* and *U* express the same assertion for him. Person *P* might come to the same conclusion. A decision on this basis, however, is unwarranted. The mere tenability of *T* and *U* cannot determine their equivalence. What we need is a concept of 'equivalence of expression' such that not all tenable assertions will be mutually equivalent. One way of obtaining this is to imagine a state of affairs in which we take *T* and *U*, in a particular situation *S*, to say something that contradicts what we believe them to say. By thinking of other possibilities and asking ourselves whether *T* and *U* in the imagined circumstances will still be tenable (or untenable), we provide ourselves with a better basis for judging whether the outlines of the content of the assertion we convey with *T* differ from those for *U*. If we find at least one possible state of affairs such that we will accept *T* as tenable and reject *U* as untenable, or vice versa, we will take this as indicating that *T* and *U* express different meaning-contents for us.

The criterion we want can be expressed as follows:

Definition of Nonequivalent Expressions. For *P* in any situation *S*, *T* and *U* are nonequivalent expressions if and only if a state of affairs can be envisaged such that *P* will accept *T* as tenable and reject *U* as untenable, or vice versa.

The states of affairs here are those that help shape what *T* and *U* express for *P* in *S*, not any states of affairs whatsoever. We examine the interpreta-

tion we have at the moment by looking for alternative expressions, not other possible interpretations of this expression considered *in abstracto*.

Let us consider a person *P* who, in a discussion about the heights of certain mountains, hears someone say, "Mount Whitecap is higher than Mount Baretop" (*T*) and another say, "Mount Whitecap is thirteen meters higher than Mount Baretop" (*U*). Perhaps *P* will think that both are true and thus 'truth-equivalent', but according to the criterion of nonequivalence, it is quite possible that *T* and *U* are nonequivalent for *P* in *S*. By envisaging changes in the heights of the mountains, *P* can come to realize that if, for example, Mount Whitecap is raised one hundred meters, *T* will be acceptable but *U* not so. In other words, *P* is able to envisage a state of affairs such that what one expression says will be true and what the other says, false. Hence, we conclude that however *T* and *U* occur in *S* (a discussion on the heights of these mountains), they will be nonequivalent for *P*.

Suppose now that someone had said, "Mount Baretop is lower than Mount Whitecap" (*V*). However one varies the mountains in one's imagination in this case, it is hard to hit upon a possible state of affairs that would make one take *V* differently from *T*—"Mount Whitecap is higher than Mount Baretop." The two expressions are, no doubt, equivalent for practically everyone in practically all situations.

As another example, take the sentences "Italians are dark" (*T*) and "All Italians are dark" (*U*). By thinking of all possible variations in the appearances of Italians, we can discover whether some appearances might be such that, if in fact Italians did look thus, we would then accept *T* and reject *U*, or vice versa. We "vary" the world and see in what possible worlds we would accept *T* and *U*. Thus, we may find we are prepared to accept *T* and reject *U* if 90 percent of Italians were dark and 10 percent fair. If this is our conclusion, then *T* asserts something less than *U*; *T* is not false even if there are some fair Italians, whereas *U* is only true if absolutely all Italians are dark. In that case, according to our criterion, *T* and *U* are nonequivalent. But one's understanding of *T* could be such that even if only 1 percent of Italians are dark, then *T* is false. Perhaps no possibility at all can be envisaged for accepting *T* and rejecting *U*; then *T* and *U* are not nonequivalent.

The importance of including in our criterion a reference to the situation *S* should be obvious, as should the reason why, when we use the criterion, we must envisage variations in the expression and its properties, not variations in the context in which the expression is given. We can mean dif-

INTERPRETATION

ferent things by the same utterance according to what kind of situation or context we express it in, even if, on some occasions, all meanings of T happen to be appropriate to the situation. But what we want to find by means of the criterion is the meaning (the equivalent expressions) for this particular situation, on this actual occasion of the expression's use.

Take another example:

$T \equiv$ Albumen coagulates in boiling water.

$U \equiv$ Albumen coagulates in water at 100° C.

At least for me, T and U would not express the same assertion in a scientific context. The statement that water boils at 100° C is true only if the atmospheric pressure is 760 mm of Hg. In cases in which the pressure varies, the assumption cannot hold. Consequently, I can think of possible reasons for denying what one expression says for me and affirming what the other says for me. This also applies to statements of the following form:

$T \equiv$ X is soluble in boiling water.

$U \equiv$ X is soluble in water at 100° C.

Water, we know, boils at temperatures well under 100° C if atmospheric pressure is low and well over if the pressure is high. Thus, the boiling point of water cannot be equated with any specific temperature such as 100° C. If X is something that dissolves in water at over 90° C, I will accept U but not T .

Of course, if X dissolves in boiling water whatever the temperature—for example, if X is surrounded by a film that bursts with the commotion stirred up by boiling water—then I would accept T . But it is conceivable to reject U at the same time, for example, if the water is heated to 120° C without boiling. If T occurs in a nonscientific context, however, I would not interpret it as above. I would take 760 mm of Hg to be implied by those who use expression T . In that case, T and U would be equivalent for me. In this example, therefore, I arrive at the following result: in situation S_1 (a scientific context), T and U are not equivalent for me, but in situation S_2 (a layman's context), they are equivalent for me.

Here is one more example:

$T \equiv X$ has a higher I.Q. than Y .

$U \equiv X$ is more intelligent than Y .

In some situations, for example, in a discussion among psychologists discussing intelligence quotients, $I(P)$ would understand U as a *less technical form* of T . I cannot then think of denying T and accepting U , or vice versa. In other situations, however, I might regard U as a less technical statement and might very well affirm one and deny the other. The sentences would then be equivalent for me in some but not all situations.

I introduced the criterion of nonequivalence to help us identify both the content of an expression and the different expressions that might express this content. *Criterion* in this context means a distinguishing mark — moreover, one with a practical application in that it enables us to decide whether or not something *is the case*. However, it would be well to note here that a consistent use of the criterion does not necessarily require us to retain the ordinary senses of the word “nonequivalent.” There may very well be cases in which pairs of sentences are deemed equivalent according to the criterion but not according to accepted usage. For the sake of simplicity, however, we assume that the criterion is used consistently even when it leads to deviations from ordinary usage. In formulating this criterion, therefore, we are specifying a definition of nonequivalence. Such a definition is what we call a “prescriptive” definition (for a discussion of prescriptive definitions, see chapter 2, pages 31–37).

Definition of Nonequivalence. We will take “Expression T in situation S , for person P , is nonequivalent to expression U in S for P ” to mean the same as “ P can conceive the possibility in S of affirming what one of the expressions expresses for him and rejecting what the other expresses for him.”

If two expressions are not nonequivalent, can we therefore say that they are equivalent? Ordinary usage would no doubt require us to answer in the affirmative. But this is not directly warranted by the definition itself. Recall that we have previously referred to our criterion as a “criterion of nonequivalence.” An example should make it clearer why.

Let T stand for “It snows or it does not snow” and U for “Hitler is dead or Hitler is not dead.” Given a situation in which these expressions occur, it

INTERPRETATION

is inconceivable that I would not accept both as valid, no matter how I vary the states of affairs they seem to say something about.

Following our criterion, I would conclude that the expressions in question are not nonequivalent. But if I were to say that insofar as they are not nonequivalent they are equivalent, I would infringe on the conventions of ordinary usage, for would anyone say that T and U express identical assertions, that is, that they are equivalent in the sense of saying the same thing? T has to do with snowy weather, U with Hitler's death. Take another example: if T stands for "No geometric bodies have extension" and U for "Some rectangles have only three sides," our verdict in all probability would be that T and U are not nonequivalent, yet not thereby equivalent. Having duly noted this complication, I can now introduce a definition of "equivalence" for two expressions T and U , on the condition that at least one of them can be considered valid if certain states of affairs hold, and not valid if certain others hold. The definition is only meant to apply if this condition is fulfilled.

Definition of Equivalent Expression. We take "Expression T in situation S for person P is equivalent to expression U in S for P " to mean the same as "Expression T in situation S for person P is not nonequivalent to expression U in S for P , and at least one of the two expressions can be thought by P to be valid if certain states of affairs hold and not valid if certain others hold."

Interpreting an Expression

It is very hard to read a sentence in one's native language without immediately giving it some interpretation. When one reads something, it is difficult, if not impossible, to confine oneself to registering only the shapes of the letters or words. Without special training, we fasten immediately onto the meaning or rather onto what we feel we understand or know to be what the words ordinarily signify. But there is no way of immediately recognizing that we have a *clear* understanding of what a sentence means, nor any way of guaranteeing that the understanding we have is the common or so-called correct one.

The way that we understand a word or a sentence is normally called "an interpretation." The fact that we use this noun, however, does not mean

that ways of understanding are accessible to observation in the way natural objects such as stones and books are accessible. We cannot compare different understandings, thoughts, or assertions directly; we can only try to indicate the difference in words and word sequences. This is the case not only when we try to make others grasp something but also when we ourselves try to grasp something. We can only proceed in a roundabout way by using different sentences. Instead of there being two distinct kinds of operations—producing a word sequence and giving an account of its meaning—we have to be content with producing two word sequences, together with the claim that the sequences have the same meaning.

Because the rules for the correct use of language are not (and never can become) exact enough to fix precisely what an expression is to mean, it is always possible to doubt what a person P means to express when he utters T in a situation S . To try to find expressions that might be equivalent to T for P in S , we can go over all the assertions we think P might have meant to express by means of T in S . We can also do the same when we want to consider every assertion that could conceivably be thought to be expressed by T , irrespective of who utters T and of the circumstances in which it occurs. We can imagine a variety of contexts for which T might be apt in different situations and for different people.

Definition of Interpretation (D_1). To say that an expression U is an interpretation of a different expression T is to say that there can be at least one person P and a situation S such that U can express the same assertion as T for P in S . Note that this definition comes under the last of our six cases of equivalence (see page 9).

Let us consider some comments that may assist in the further precization of the term “interpretation.” For two expressions to be characterized as different, they need only have nonidentical words or word sequences. Furthermore, the word “can” in the definition signifies that T and U need not necessarily have occurred as equivalent expressions. The sense of the definition can therefore also be rendered by the following: “It is practically conceivable that at least one person means the same by T and U in some situation.” We do not need to be able to specify the person or the situation; it is the *possibility* that counts. Perhaps the concept would have been more immediately clear to the reader if I had used the phrase “possible alternative

INTERPRETATION

expression for” instead of “interpretation of.” The point is that what makes an expression a possible alternative is that it is equivalent to the original expression for at least one person in some situation, and the term “interpretation” is chosen simply because it is shorter. As long as we keep the wording of the definition in mind, no misunderstanding should arise.

From D_1 it follows that T is always an interpretation of T and that if U is an interpretation of T , then T is an interpretation of U . But it does not follow that if U is an interpretation of T and V is an interpretation of U , then V is necessarily an interpretation of T . Different interpretations of an expression need not be interpretations of one another, even if there are some situations in which they are.

Since there are cases in which T and V are interpretations of U but not of each other — that is, counterexamples to the statement that if U is an interpretation of T and V an interpretation of U , then V must be an interpretation of T or vice versa — we should describe the relationship of interpretation in logical terminology as *intransitive*. It is also *symmetrical*, since if T is an interpretation of U then U is an interpretation of T , and *reflexive*, since all interpretations are interpretations of themselves.

In the following, I use T_0 to symbolize an expression that is to be interpreted and T_1, T_2, \dots, T_n to symbolize possible interpretations.

Frequently, we fail to catch on to what someone says or writes. In such cases, although we are not in a position to answer yes or no, agreed or disagreed, we can still reply with conditional sentences of the following kind: “If by T_0 is meant T_1 , then T_0 is acceptable (true or valid). But if by T_0 is meant T_2 , then T_0 is unacceptable (false or invalid). If by T_0 is meant T_3 , then . . . and so on.” For example, take T_0 to be “The constitutional law of 1814 denied Jews entry into Norway.” If by T_0 is meant that the constitutional law of 1814 denied upholders of the Mosaic Law entry into Norway, then T_0 is acceptable; that is how the constitutional law is interpreted. If, however, by T_0 is meant that the constitutional law of 1814 denied every Jewish person entry into Norway, then T_0 is unacceptable; according to the interpretation of the law, *baptized* Jews still had entry into the country.

Setting Forth Possible Interpretations

If we take a situation S as constant, we can set about finding interpretations for a given expression T in S by thinking of various speakers and listeners in

S. Alternatively, we can think of the speakers and listeners as constants and vary the situation; or we can take both the people and the situation as constants and ask ourselves what expressions could convey the same as *T*. All three of these are ways of making interpretations in the sense introduced previously.

Simply from what D_1 says, one might think that it was comparatively easy to set up long lists of different interpretations of an expression. If *S* or *P* are taken as constants, however, it may not be so easy. The more fully one specifies a situation and a linguistic context, the fewer the possibilities of interpretation. Even so, there always seem to be some alternatives. For a given person in a given situation, there still seem to be a number of different ways of conveying one and the same assertion, that is, there usually exist a number of different, but equivalent, expressions.

When *P* is a close acquaintance and he is talking about something we have often heard him talk about, and the topic is also one in which misunderstanding can easily be detected, our interpretation emerges in part from our own special knowledge of *P*. As a special case, we can even suppose that we, ourselves, are *P*. But in the absence of such exceptional conditions, where no such special knowledge can be drawn on, our interpretations depend more on a common experience of the use of language. Even when we interpret an expression in a definite context we are drawing on our experience of many other contexts.

When trying to interpret a given expression *T*, we often have to consider *T* in a variety of contexts. What kind of discussion could *T* arise in? In a newspaper or in a technical or political journal, or some other source? What are the consequences of denying or accepting *T*? If two close friends of mine do not agree about *T*, what misunderstandings might exist that could explain this disagreement? If *T* occurs in a newspaper that leans toward one political party, how should we expect a newspaper that leans toward another party to interpret the expression? The examples are endless.

Reasonable Interpretations

When we have some information about the context in which an expression *T* occurs, we are able to distinguish between reasonable and unreasonable interpretations of *T*. For example, the expression “*U* is a *reasonable interpretation* of *T* when *T* occurs in *S*” means the same as “When *T* occurs in *S*, *T*

INTERPRETATION

usually means the same as U .” The equivalence between T and U in S implies that U is an interpretation of T according to D_1 . In addition to this, U will be a ‘common’ interpretation, that is, the people or groups for whom T and U are equivalent will not be too few or too specialized.

By “ T_1 is a correct interpretation of T_0 ,” one often means that T_1 expresses the statement that T_0 serves to express in the context in which T_0 occurs. We must also note here that T_1 may well be given alternative interpretations by different people. Therefore, a better rendering, with the reference to the person made explicit, would be “ T_1 , as I (P_1) interpret T_1 , is a correct interpretation of T_0 ” and “ T_1 expresses, according to my (P_1)’s interpretation, the same assertion as T_0 serves to express.” It is easy to forget this reference to a person when using an expression of the kind “ T_1 is a *correct interpretation* of T_0 .” One should remember, however, that quite different expressions T_2, T_3, \dots, T_n , that are also “correct” for P_2, P_3, \dots, P_n , and that these other expressions can be quite *incorrect* according to P_1 ’s understanding, that is, for him they do not mean at all the same as T_0 .

The expression “ T_1 is a correct interpretation of T_0 ” may be misleading in another way. “ T_1 is a correct interpretation” might appear to be exchangeable with “ T_1 expresses an acceptable assertion.” However, T_1 can very well be a correct interpretation even though it does not express an acceptable assertion. For example, if T_0 is “Richmond Hill is higher than Mount Everest” and T_1 is “Richmond Hill, not counting the depth of snow that may lie on it, is higher than Mount Everest,” T_1 will, for me, be a correct interpretation of T_0 even though I would not accept it. Conversely, a very unreasonable interpretation may express an assertion that one does accept.

Interpretation of Expressions Used as Terms

Examples of terms include “Caesar,” “pencil,” “Constitution,” “to the west of,” “the highest volcano in Denmark,” and “being at a loss for words.” “Constitution” denotes the constitution of, say, the United States or Great Britain; the constitution itself is not a term. “The highest volcano in Denmark” is a term that has no denotation since there are no volcanoes in Denmark, but the term still expresses something.

A term “ a ” is said to denote something if a exists. Otherwise it doesn’t denote anything. Provided only that “ a ” has a sufficiently clear sense, “ a ” expresses something, whether or not a exists. “Perpetual motion,” and “pri-

primordial language” are terms that probably denote nothing, but they can express things that we are able to think about even if they do not exist. If in fact there once existed an original language from which language as we now know it has evolved, then that language is what the term “primordial language” denotes. A term “*a*” can be said to denote something so long as *a* existed or will exist, even if *a* does not exist at the time we are using the term.

With regard to the parts of sentences that cannot themselves be construed as sentences, our interest here is mainly in terms. Logically, the crucial difference between a term and a sentence is that a term cannot by itself express a statement. To state something, you have to say something about something, and for this you need a sentence. Separately, the terms “Camembert” and “smells” do not express a statement, nor must they together since “Camembert smells” may still be only a term and not a sentence. Together, however, they can be construed as a sentence, although of course they need not be.

In examining the possible interpretations of an expression, there is usually a comparatively determinate part of it—one or more words—that suggests the most significant candidates for interpretations of the expression as a whole. In such cases, it may be helpful to examine separately the different meanings that this determinate part can have, first as part of different expressions and second as part of the expression in which it appears.

It is essential to be clear about our purposes: is it to interpret terms or expressions by themselves or as components in sentences? Many otherwise reasonable interpretations of a word can be ruled out immediately once we are given the rest of the sentence in which the word occurs. However, setting a word in a sentence may just as easily call to mind new interpretations. Note that when interpreting a sentence, it is a common mistake to interpret the parts of the sentence as though they were in fact separate.

In the following definition, the interpretation of terms occurring in expressions is restricted to the interpretation of them as they occur *in* expressions, that is, to the interpretation of the expressions themselves.

Definition of terms that are interpretations of each other (D_2). That one term “*a*” is an interpretation of another term “*b*” in an expression *T* means that there is an expression *U* that is an interpretation of *T* and which is made by substituting “*b*” for “*a*” in *T*. For example, “popular rule” can be an interpretation of “democracy” because the sentence “Our

INTERPRETATION

country has popular rule” is an interpretation of “Our country has a democracy.”

Many terms can be given a wide range of meanings only if one thinks of them in isolation from context. The occurrence of a term in an expression limits its range of meanings and thus also the danger of confusion. If a term “*b*” does have a variety of meanings, it does not follow that the expressions for these will be different interpretations of “*b*” when “*b*” occurs in a given sentence. If someone says “He’s a shark” or “Only a shark would do that,” naturally we do not interpret “shark” in the zoological sense. Similarly, with the term “motive power” in the expression “Egoism is man’s strongest motive power,” we should not take it to mean the kind of power that is used to propel vehicles.

Depth of Intended Meaning

I have used the term “misunderstand” in rather a wide sense. Our understanding of someone’s thoughts can be more or less deep. Still, it would be wrong to envisage a maximum depth that can be plumbed. Usually the best we can do is, by systematically questioning a person, to discover where the similarity between our own and his understanding begins and ends. In this way, we can at least discover various points at the boundaries between our respective understandings. Accuracy must remain a matter of approximation. In practice, we find that we are less concerned with establishing as exact an understanding as possible than with eliminating all the possible unfortunate misunderstandings we think may arise. Then again, because our mental capacities are partially dependent on memory, our desire to arrive at a full grasp of the significance of some statement is often frustrated by an inability to recall something. In school and in college, we are bombarded with a great number of expressions that our teachers assign much meaning to, but as students we may do little more than learn the sound of them. We make few attempts to understand their full significance, and even if we do try, perhaps our capacity to do so is still too weak. Possibly this is less the case in mathematics, where one manages to clarify what one hears by working out examples and “seeing” how they work, but in the less exact and more discursive sciences, we accumulate a great number of ab-

abstract expressions that cannot be elucidated in the same way. Our understanding of these expressions often remains inadequate and superficial.

A sentence such as “The world is surrounded by a gravitational field” can mean very little or a great deal. What it means to a physicist, a high school student, and a seventy-year-old former university student will vary in comprehensiveness as well as in substance. The physicist may have reflected for years on the question of gravitational fields, and he will be at home in the whole complex of considerations that, at his level of understanding, go into this sentence. Variations in level of knowledge, interest, and intelligence inevitably result in variations in the depth and clarity of a person’s grasp of what he reads or hears.

To measure your own level of understanding a sentence, try the following test: simply read the following sentence without reflecting on it. “There was a 30 percent failure in the philosophy exam last summer.” Now answer the following series of questions: do you understand by T_0 the same as you understand by T_1 , that “There was a 30 percent failure in the philosophy exam last summer among those who signed up to take it”? If you can honestly answer either yes or no, then you can give yourself a point for depth of understanding. If your answer was yes, then you can go on to answer this question: do you count as failing those who signed up to take the exam but did not attend it? If you can honestly answer yes, then give yourself another point. In that case, however, your use of language must be regarded as extraordinary—not the least by those who might have been prevented by sickness from attending the exam and who would hardly care to be described as having failed. If you answered no, you also get another point, although here you will come up against some difficulties that we must leave aside for the present. Next, answer the following question: do you understand by T_0 what you also understand by T_2 , that “There was a 30 percent failure in the philosophy exam last summer among those who attended the exam”? If your answer is an honest yes or no, you get another point. If not, you get one deducted; by not being able to answer either yes or no, your understanding of T_0 must be regarded to that extent as imprecise or vague. (Of course, it could be that you considered T_0 to be ambiguous, but for simplicity’s sake, we shall avoid such complications for the moment.) If you answer yes to that question, then answer this one: Do you count as failures those who attended the exam but withdrew as soon as they saw the exam

INTERPRETATION

paper? Other examples can invite a far greater number of interesting possibilities for interpretation and a correspondingly longer list of questions. Here at least we get a firsthand glimpse of the distinction between higher and lower levels of understanding an expression.

Finally, consider the following short list of differences in interpretation:

$T_0 \equiv$ Male students perform better than female students on the philosophy exam.

$T_1 \equiv$ Male students, on average, get higher marks on the philosophy exam.

$T_2 \equiv$ A higher percentage of male students pass the philosophy exam.

$T_3 \equiv$ The percentage of female students who fail is greater than that of male students who fail.

$T_4 \equiv$ Men perform better than women on the philosophy exam.

II

Precization and Definition

Language as an Instrument for Precization

I have already mentioned that everyday language habits are in many ways inadequate when it comes to conveying every inflection and gradation of meaning. We find that just as special techniques are needed in other fields of technology, we also need special tools and training to facilitate clear thinking and efficient communication. The approach discussed in this book is based on ordinary language, but in important respects, we must go beyond everyday usage, even to the extent of importing whole systems of new words and, in some cases, new rules of grammar.

The technical language of chemistry, physics, and biology is integral to the development of these sciences. Indeed, modern science is intelligible only to those who have learned at least some of this special language—access is limited to those individuals whose use of terms presupposes a greater depth and clarity than is required in everyday life. An adequate scientific account contains only expressions with comparatively fixed and clearly defined meanings, which means that it tends to be understood in much the same way by anyone who understands it all, that is, by anyone conversant with the terminology and concepts in question.

The degree of preciseness we find in science is the product of hundreds of years of careful and consistent logical thought. Experiment, observation, and inventiveness are not enough for the building up of knowledge. Together with these go logic, conceptual analysis, and precization, an aptitude for which must be acquired by all who hope to understand and make use of the results of scientific progress.

Technical language has its own set purposes and is often useless in everyday life, even to its creators. Extreme accuracy in itself can be both an obstacle to daily discourse and a sheer waste of time. A nicely crafted scientific

PRECIZATION AND DEFINITION

statement can, if used unjudiciously, become ambiguous or vague, whereas colloquialisms, even inarticulate exclamations, can in certain settings be quite clear. Someone who has had no practice in photography may often get better pictures with a cheap apparatus than with the refined equipment of the expert simply because he does not know how to make the necessary fine adjustments. In any case, a snapshot may be all that is required. A person can act wisely even if he is not adept at giving verbal accounts of what he does and why he does it. Politicians and businessmen often exhibit a high degree of intelligence in their behavior, although their own accounts of what they do can be hopelessly jumbled or trite. Literal interpretation of the words of “important” people often results in fruitless discussion, for their importance is frequently unrelated to their ability to express themselves.

A clear understanding of language as a precise instrument for thought need not blunt our sense for the other functions of language. Indeed, our appreciation of language as a whole depends on learning to distinguish between its separate functions. Without an awareness of such distinctions, we may fail to appreciate the values peculiar to poetic or purely scientific utterances; we may be led to make inappropriate demands for precision in poetry and for stylistic considerations in science. Consideration of style alone, for example, might require a writer to vary the term used to denote the same thing, but in scientific accounts this can only lead to a lowering of the level of preciseness.

Precization Defined

In serious discussion, we want to eliminate all expressions that experience tells us are vulnerable to misinterpretation. We try to replace them with other expressions or else explicitly restrict our use of such expressions by giving them definitions that apply to the discussion at hand. In such a case, when we replace an expression T with another expression U without departing from the topic, we can generally assume that U is intended to be a more precise expression of the statement it expresses than T —that is, U is a precization of T .

Definition of Precization (D_3). That expression U is a precization of expression T means that all reasonable interpretations of U are reasonable interpretations of T and that there is at least one reasonable

interpretation of T that is *not* a reasonable interpretation of U . This definition can be expanded to include terms as well.

D_3 can also be formulated as follows: that expression U is a precization of expression T means that there is at least one reasonable interpretation of T that is not a reasonable interpretation of U and that there is no reasonable interpretation of U that is not also a reasonable interpretation of T .

We can now establish that the following four expressions mean the same in this book: “ U is more precise than T ,” “ U is a precization of T ,” “ T is less precise than U ,” and “ T is a deprecization of U .”

If U is a precization of T , then according to D_3 it follows (among other things) that every reasonable interpretation of U is a reasonable interpretation of T . In particular, it follows that if U is a reasonable interpretation of U , then U is a reasonable interpretation of T . However, we already know that ‘is an interpretation of’ is a reflexive relation, that is, that all expressions are interpretations of themselves. Consequently, U must be an interpretation of U and, in this case, also of T . Thus, we see that precization is a special case of interpretation.

Although precization is a form of interpretation, the formal structure of the relation of precization is quite different from that of the relation of interpretation. If we substitute U for T in D_3 , we see that U cannot be a precization of U . ‘Is a precization of’ is therefore a *nonreflexive* relation. Furthermore, if U is a precization of T , then T can never be a precization of U . Thus, ‘Is a precization of’ is an *asymmetrical* relation. Finally, if U is a precization of T and T is a precization of V , then U is always a precization of V . Thus, ‘is a precization of’ is a *transitive* relation as well. (Recall from chapter 1, pages 16–18 that ‘is an interpretation of,’ in contrast, is a *reflexive*, *symmetrical*, and *intransitive* relation.)

If we are to decide whether or not U is a precization of T , we must ask ourselves the following series of questions: (1) Is U a reasonable interpretation of T ? If the answer is no, U cannot be a precization of T because every precization of T , according to the above reasoning, must be an interpretation of T . If the answer is yes, we must go on to ask, (2) Is there some reasonable interpretation of T that is not a reasonable interpretation of U ? If the answer is no, U must be rejected as a possible precization. But if we believe we can point to such an interpretation, we must go on to ask, (3) Can we find a reasonable interpretation of U that is not a reasonable interpreta-

PRECIZATION AND DEFINITION

tion of *T*? If we find such an interpretation, then *U* must be rejected as a possible precization. If we are unable to discover any reasonable interpretation of *U* that is not also a reasonable interpretation of *T*, then we can conclude that *U* is more precise than *T*, that is, *U* is a precization of *T*.

The term “precization” applies both to the expressions and terms we introduce as more precise than some other expression or term and also to the actual *process* of constructing these expressions. In everyday language, we can find many expressions, such as “clearer,” “more transparent,” “not so obscure,” and “less misleading” that convey roughly what is meant here by “more precise.”

We should note that the expression “*T* is *less precise* than *U*” is not exchangeable with “*T* is *a more general statement* than *U*.” Thus, although the sentence “All men are musical” is more general than “Only a few men are musical,” it need not be less precise. To generalize a statement is to make it apply to all members of a class rather than to specific members of it. Rash general statements are often false, but they are no less precise for being more general; they are just more comprehensive. According to our technical sense of “precise,” a pair of statements such as (1) “All positive whole numbers are divisible by 2” and (2) “All positive whole numbers over 1,000 are divisible by 2” are not comparable with regard to preciseness because they each have different reasonable interpretations. It would be hard to think of some reasonable interpretation that they had in common.

Consider another pair of statements: (3) “A characteristic of Ibsen’s work is its rigorous formal structure” and (4) “A characteristic of Ibsen’s greater works is their rigorous formal structure.” The relationship between (3) and (4) is, as with the previous example, one of degree of comprehensiveness. Generality does not exclude preciseness; this is fortunate, for if it did, we would be unable to give concise and exact expression to even ordinary bits of knowledge.

We must also not confuse the degree of preciseness of an expression with its tenability. We would most likely admit that the expression “Mozart was musical” expresses a tenable assertion in whatever way we interpret the term “musical,” but this does not necessarily indicate that the term “musical” is an especially precise one. On the contrary, it is only because we cannot conceive of any way in which Mozart could possibly *not* be described as musical that we do not ask here for a precization of *musical*. However, if

someone describes a small child as musical, we would almost certainly want to know whether the child in question was an infant prodigy or whether it was just that he smiled when he heard someone humming a tune. With “Mozart was musical,” however, one tends to subscribe straightaway to any unformulated assertion that can be a precization of it.

Yet another incorrect use of the technical term “precize” would be in contexts for which “specify” would be the more appropriate term. An expression U can be used to specify another expression T if U asserts what T asserts but at the same time asserts *something more* about the same subject matter. The warning about confusing “less general” with “more precise” also applies to “more specific.” Any difference between “less general” and “more specific” arises, *inter alia*, from the fact that a general statement is typically used to draw attention to the *similarities* among distinct objects while a “specification” draws attention to the special properties peculiar to distinct objects themselves. “Less general” does not imply “more specific.”

To illustrate the process of precizing, we can say that in answering the question as to whether T_1 is more precise than T_0 (in the list at the end of chapter 1, page 24) we should produce a reply such as the following: “There are many ways in which a person can be better than another. One of them is to get higher grades in school. An expression specifying that a person is better than another in this respect is more precise than one that does not mention any circumstances at all. It both gives more information and allows one to accept or reject the assertion on the basis of the information it provides.” Note that in the case of *specifying*, however, the added information does not serve to identify assertions in this way; it only adds more to an assertion that is already identified. We could put it like this: The fact that the expression “gets higher grades than” is a *precization* of “better than” does not depend on its being more *specific*, although it is obviously that, too. It depends on the added information having the potential to enable us to choose correctly one assertion from a whole list of unformulated ones, all of which are possible and distinct interpretations of T_0 .

Of course, an expression that is a precization of another expression for some people may for others be a specification or a generalization of the same expression. For example, for some people, the expression “He is going to Washington” (T) may be only a specification of the expression “He is going” (U), whereas for others who are more likely to interpret U as saying that

PRECIZATION AND DEFINITION

Figure 3. Relationships between two expressions, T and U .

someone is dying, T will be a precization of U . Although all interpretations of T will be possible interpretations of U , U has at least one interpretation that, in this context, T does not have.

The meaning of ‘is more precise than’ can be illustrated with the help of circle diagrams. If we represent all reasonable interpretations of T as contained within one circle and all reasonable interpretations of U as contained within another, we get four possible relationships between the circles (figure 3).

In case I in figure 3, there are no reasonable interpretations of U outside the domain of T ; all of them lie within T . This illustrates the case in which U is more precise than T . Case II illustrates the situation in which T and U allow exactly the same reasonable interpretations; there are no reasonable interpretations of T that are not also reasonable interpretations of U and no reasonable interpretations of U that are not also reasonable interpretations of T . In case III, T and U have some reasonable interpretations in common and some that are confined to each of them; according to D_3 , then, neither one can be more precise than the other. Because they cannot be similarly precise, they cannot generally be regarded as comparable with respect to preciseness. Case IV illustrates the most common situation: T and U are two randomly chosen expressions for which, as a rule, there are no reasonable interpretations in common. As in case III, they cannot be compared with respect to preciseness.

Two expressions, T and U , are incomparable with respect to preciseness if, and only if, each T and U have at least one reasonable interpretation that the other does not have. For two expressions to be incomparable with respect to preciseness, it is only necessary that each expression has at least one reasonable interpretation not shared by the other. If expression U is a precization of expression T , then T will have more reasonable interpretations than U , granted that U has a finite number of interpretations. According to D_3 , if U is a precization of T , each reasonable interpretation of U is also a

reasonable interpretation of *T*, and *T* has, in addition, at least *one* reasonable interpretation that is not a reasonable interpretation of *U*. To find merely that expression *T* allows a greater number of reasonable interpretations than expression *U* is not in itself sufficient evidence that *U* is a precization of *T*. The necessary and sufficient condition is as given in *D*₃.

Finally, if, as often happens, one person judges *U* to be more precise than *T* in situation *S*, while in the same situation *S* another person judges *T* to be more precise than *U*, the only way to decide who is right is to make systematic observations of language customs in *S*.

Prescriptive Definitions

When we precize a term “*b*,” we provide less ambiguous terms for something that “*b*” sometimes, but not always, expresses. Precizations do no more than describe a segment of already existing language habits; they introduce no proposals for changing these habits. This section considers a kind of statement that is concerned not with describing language usage but with altering it.

The difference between describing and prescribing is a familiar one. If we say that no one is to be considered an adult until he is sixteen years old, we are stating a rule. If one person at fifteen is, in fact, more “adult” than another at sixteen, this does not make the rule false or invalid, only silly. However, if one says that someone at sixteen years of age is, in fact, more adult than another person at fifteen, one purports to describe a state of affairs, and this claim could certainly be false.

There is an analogous difference between describing and prescribing language usage. When we say that term “*a*” often has the same meaning as term “*b*,” we are *describing* a usage. But if we say that term “*a*” in a certain context is to mean the same as term “*b*,” we are *prescribing* a usage. We make a rule our listeners must follow if they are to be clear about what we say. I will call such a rule a “prescriptive definition.” The purposes of prescriptive definitions are discussed in more detail in the next section. Here it is enough to say, briefly, that their most common use is to replace long and complicated expressions with shorter and simpler ones.

The word “definition” comes from the Latin *definitio*. The verb is *definire*, which means to “set limits to” and hence to delimit the meaning of terms. Generally, the etymology of a word provides no reliable indication

PRECIZATION AND DEFINITION

of its use in contemporary speech, but in this case, the word's technical meaning represents both a deepening and a precization of the original Latin.

In this book, the word "definition" occurs both by itself and in compound expressions such as "prescriptive definition," "descriptive definition," and so on. When it occurs by itself, it is being used as an abbreviation for "prescriptive definition."

Definition of Prescriptive Definition (D_4). By "prescriptive definition," we mean a definition that requires an expression T in a certain specified context, or in all contexts, to be interpreted in the same way as another expression U .

Expression T is called the *definiendum* (that which is defined) and U the *definiens* (that which defines). We can formulate what we mean by *definition* in the following way: " $T =_D U$ in S " or " T , by definition, is to be synonymous with U in context S ."

With regard to D_4 , when a definition is proposed for only a particular context, its application is often restricted to specific chapters or works in which the term in question is used. Definitions can be proposed even though it is fully realized that they would be inadequate in other contexts.

In setting up a definition $T =_D U$, it is likely that U was already an interpretation of T even before it was called into service as a definition, but this is not always the case. A definition aims at limiting the use of the *definiendum* (T) to those cases for which the *definiens* (U) specifies our usage of the term, and it is quite possible for T to be defined by U without previously having been a possible interpretation of it, or without U already being an interpretation of T . Of course, if T is an entirely new expression, there is little likelihood of confusion and U may gradually become established in common usage as an interpretation of T . (Note in this context that it is not a prescriptive definition itself but rather a *definiens* that can be an interpretation of the *definiendum*.)

Whether the context is a scientific one or not, it is a common malpractice to introduce formally a prescriptive definition and then quickly forget it or fail to follow it consistently. After first stating that T in context S will always mean the same as U , one ends up by using T in some other way. This is a readily avoidable source of confusion. It can also happen that, having given a prescriptive definition and used it for a while, one finds that it is not

suitable. The thing to do then is to indicate one's decision to give up the prescriptive definition in the hope of eventually producing a new and better one.

To propose a definition of expression T is the same as to propose that T be interpreted as U , which according to D_1 implies that T and U shall be treated as cognitively equivalent expressions. In other words, one proposes that, in some linguistic context, T is to be replaced by U and that U can be substituted for T without change of meaning. To be sure that the expression U interprets expression T in accordance with one's intention, it is a good rule to strike out T in the text and substitute U to see if there is any change in meaning.

Two Examples of Prescriptive Definitions

My first example of a prescriptive definition is the expression D_4 . With this I clearly state that, in this book, the term "definition" is to be interpreted in the same way as the longer expression provided. This longer expression is probably a good deal more precise than the word "definition," but it is more convenient to use the simple word "definition," especially since it is already often used in much the same way as the longer expression.

A second example of a prescriptive definition is provided by the Norwegian law on labor disputes, which begins by defining some terms:

1. A worker — anyone who in return for money undertakes work of whatever kind for:
 - a. a private employer.
 - b. the state or municipality, provided he works by agreement or with a notice-of-termination period of fourteen days or less, and provided he is not to be considered a public servant.
2. An employer — anyone who employs one or more workers.

Here we are given a definition of the word "worker" in terms of a long expression. (According to this definition, the term "worker" probably covers more than the usual sense of the term. The head of a department, for example, would be a worker according to the definition, as long as he can give two weeks' notice.) The definition of the word "employer" makes use of the definition of "worker." The *definiens* in the definition of "employer" should

PRECIZATION AND DEFINITION

then read: “anyone who employs one or more persons, who in return for money. . . .” This in turn can come into the definition of “worker” (1a), and so we end up in a circle.

As mentioned earlier in this section, there are different kinds of definitions. An expression that is formulated as a definition, or is explicitly stated to be a definition, can often be interpreted as follows:

1. A description of the meaning of another expression or term.
2. A proposal (or sometimes a report of a proposal) about how an expression is to be interpreted in terms of another expression or term.
3. A combination of 1 and 2.
4. An assertion that some property is essential to or especially characteristic of this or that object.

A sentence of type 1 was characterized earlier as a descriptive definition. A sentence of type 2 was just characterized as a prescriptive definition. A sentence of type 4 is often called an “essential definition” or “real definition.” However, none of the uses of the term *definition* as indicated by 1, 3, and 4 coincide with that given by D_4 . Definition D_4 constitutes a precization of our usage in the way indicated by 2.

Example of Definition 1

Consider a quotation from political scientist James B. Bryce in his book *Modern Democracies*: “Democracy really means nothing more nor less than the rule of the whole people expressing their sovereign will by their votes” (Bryce 1921, vol. 1: vii). This assertion occurs in an analysis of the actual content of so-called democracies (before 1930) and gives to all intents and purposes a precization and description of the typical usage in professional literature on this subject.

Consider, too, the following: “During recent years such terms as economic democracy and industrial democracy have been used to describe a system under which the many would control business as well as politics” (Nearing 1945: 23). The first words in this description of usage delimit — though roughly — the area the definition is thought to cover.

In a psychology book we find the following: “Psychology means ‘learning about the self.’ But what is the ‘self’? Some understand the self as a self-

sufficient essence, so fundamentally different from the body that after death it is able to lead its own life, independent of all that is corporeal.” The first sentence of this passage is probably intended as a precization of the word “psychology” for those not already acquainted with its use. The third sentence, however, seems to mention a property of the self (according to some), not a piece of information about some people’s usage, and we should therefore call it a real definition. If this accords with the author’s meaning, the following refinements and revisions are justified:

“Psychology” means the same as “learning about the self.” But what is the self? Some understand by the ‘self’ . . .

The use of double and single quotation marks allows us to indicate the fact that the first sentence covers the word “psychology,” while the second and third sentences cover the self and the concept ‘self,’ although the distinction is by no means a clear one. (See the threefold distinction illustrated in figure 1.)

Example of Definition 2

In *Human Knowledge*, Bertrand Russell (1948: 113) writes: “‘Belief,’ as I wish to use the word, denotes a state of mind or body, or both, in which an animal acts with reference to something not sensibly present.” Here Russell clearly indicates that however others use the term ‘belief,’ he is going to mean by it what he takes both himself and his readers to mean by “a state of mind or body, or both, in which an animal acts with reference to something not sensibly present,” a *definiens* that he then proceeds to clarify with examples: “When I go to the station in expectation of finding a train, my action expresses belief. So does the action of a dog excited by the smell of a fox . . .” and so forth.

Example of Definition 3

Under the heading “Price Index. 1. Definition” in a textbook of economics, we find the following definition that looks as if it were also a description: “By price index one means a common expression for the average height of the different goods’ prices in a land, measured in proportion to

PRECIZATION AND DEFINITION

prices in a given former year.” The author describes what is meant by “price index,” which means that he is concerned here with a description of usage. But the sentence occurs in a context that makes it probable that he also wants to make clear in this sentence what particular usage he intends to follow in his textbook. This indicates that it is an instance of the composite definition 3.

Example of Definition 4

The sentence “Democracy essentially means freedom of expression for every individual” may be meant to express something especially characteristic of democracies. In the same text, a definition of “democracy” may be offered in terms of a form of government. A shorter sentence, “Democracy means freedom of expression,” may also, in certain contexts, plausibly be interpreted as an assertion that freedom of expression is essential or especially characteristic of a democracy.

It is important to be able to distinguish among definitions 1, 2, and 3. Often, however, the context gives little indication as to which of them is most reasonable in a given case. It is particularly important to separate real and prescriptive definitions 4 and 2, if only because when a prescriptive definition is required for an expression, real definitions are of no value, however profound they may be. The understanding of a real definition presupposes that the *definiendum* and *definiens* are interpreted in a fixed way. As long as words are vague and ambiguous and therefore in need of prescriptive definitions, real definitions are not suitable. It is not enough that the expressions have a fairly determinate meaning for the speaker if this meaning is not understood by the audience.

It is easy to envisage how a grasp of definition theory can prevent chaos and inconsequence in the course of discussion. Suppose someone proposes a prescriptive definition for the use of an expression in a discussion and then another person gets up and says the first is mistaken, that the definition is stupid and does not accord with the expression’s real meaning, and that he himself has the “correct” definition. We might reasonably assume either that the second speaker has not understood that the first meant to give a prescriptive definition or that the distinction did not occur to him. If the objector, however, declares that the definition is inadequate or unserviceable, his objection might well be a pertinent one.

Debates often give rise to exchanges of the following pattern: P_1 asserts T_0 , and P_2 replies that it is a question of definition whether one accepts or rejects T_0 . Now, P_2 can reasonably be assumed to be asserting two things. First, T_0 , in the situation at hand, allows for at least two reasonable interpretations, T_1 and T_2 , and T_0 is tenable if interpreted as T_1 and untenable if interpreted as T_2 . Second, a discussion can proceed only after a decision, in the form of a prescriptive definition, is made that will allow us to determine whether T_0 is to be interpreted as T_1 or as T_2 .

If one wants to avoid a dispute about which prescriptive definition to apply, one can take a conditional position toward T_0 : “If P_1 by T_0 means T_1 , then I agree; if T_2 is meant, then I disagree.” Let us observe an example of this:

We are told about a certain Valentin Sjerepanov that he “died, but is now alive.” On March 3, 1944, at 2:41 P.M., his breathing had ceased, his heart had stopped beating, his reflexes had gone, and yet he undoubtedly came back to life again. Here we might plausibly say that it is simply a matter of definition whether one accepts the possibility that the expression is true. For certain prescriptive definitions of “dead” and “alive,” the proposition will be analytically untenable; for others it will be synthetic (see chapter 3, pages 55–57, for a discussion of “analytic” and “synthetic” expressions). If the proposition is held to be self-contradictory on the basis of rules of language, it cannot be true—whatever may have actually happened to Sjerepanov.

Why Precize or Define?

In this book, I am focusing on the significance of the process of precizing in actual discussion. But precization is also relevant to the clear stating of problems and, indeed, to all thinking whatsoever. To take an obvious example, consider the question of so-called pseudo-problems, that is, problems that, when rephrased or precized, seem to express either some quite different problem or else a truism. We know that since the beginning of early Greek civilization, people have discussed whether the problems philosophy considers are pseudo-problems—and this question has even been raised in connection with the special sciences.

In *Essays in Pragmatism*, William James (1907) tells us of an elementary example of a pseudo-problem. It is mentioned here only to illustrate what a

PRECIZATION AND DEFINITION

pseudo-problem is, not because it is particularly profound or of any practical consequence.

Some years ago . . . I returned from a solitary ramble to find every one engaged in a ferocious metaphysical dispute. The *corpus* of the dispute was a squirrel — a live squirrel supposed to be clinging to one side of a tree-trunk; while over against the tree's opposite side a human being was imagined to stand. This human witness tries to get sight of the squirrel by moving rapidly round the tree, but no matter how fast he goes, the squirrel moves as fast in the opposite direction, and always keeps the tree between himself and the man, so that never a glimpse of him is caught. The resultant metaphysical problem now is this: *Does the man go round the squirrel or not?* . . . Every one had taken sides. . . . Mindful of the scholastic adage that whenever you meet a contradiction you must make a distinction, I immediately sought and found one, as follows: "Which party is right," I said, "depends on what you *practically mean* by 'going round' the squirrel. If you mean passing from the north of him to the east, then to the south, then to the west, and then to the north of him again, obviously the man does go round him. . . . But if on the contrary you mean being first in front of him, then on the right of him, then behind him, then on his left, and finally in front again, it is quite obvious that the man fails to go round him. . . . Make the distinction, and there is no occasion for further dispute." (James 1948: 141)

These two distinct precizations express two quite different assertions, both of which, in the case cited, the company apparently agreed to — apart from some obstinate dissenters who would have nothing of precization and other hairsplitting and maintained that the man either did or did not go around the squirrel.

Precization is also useful for bringing out the depths of an expression's meaning since it implies that there is a thought to precize. Mindless chatter cannot be precized. The attempt to render an expression precise may therefore be a way of finding out whether we mean anything at all when we use it. With practice, we can become better at distinguishing between an articulate and a superficial grasp of what an expression means. Such a skill enables us to appreciate the richness and subtlety of intelligent remarks, just as it equips us to see through the shallow glare of catchphrases and propaganda. Furthermore, precization can have thoroughly practical applications.

In recent years, opinion polls have come to play an increasing part in social life. Through interviews and questionnaires, one tries to get as accurate a picture as possible of the general public's attitude to certain questions

of social significance. The vast expenditure of time and energy devoted to these investigations could easily be wasted in view of the difficulties involved in predicting ambiguities in the questions put to the public. Systematic inquiries can, however, be conducted so as to discover the most important sources of misunderstanding in any given questionnaire, but difficulties must also be faced when interpreting the answers obtained. In spite of every safeguard, people still seem to answer questions other than those being asked, and as long as they are unaccustomed to formulating reasonably precise and complex expressions, they will be unlikely to give any reasonably precise answers.

The aim of definition is different from that of precization. If we discover that an expression can be interpreted in two ways and that serious misunderstandings occur every time speaker and listener interpret it differently, there can be no profitable discussion as long as that expression continues to be used. However, if a precization that does eliminate differences in interpretation is too complicated (e.g., uses ten to twenty times as many words as the original), it will likely be too clumsy. In that case, what we need is a definition. A definition can explicitly state that the original expression is to be used in the sense provided by one of the long precizations; once this is clear, we can safely keep to the original and more handy expression.

Even if the difference in complexity between *definiens* and *definiendum* is slight, a definition can still be appropriate. In train timetables, for example, instead of expressions such as "8 A.M." and "8 P.M.," some countries use "8:00 hours" and "20:00 hours." The number "8," because of its horological ambiguity, can give rise to much inconvenience, and so to avoid unnecessary confusion, definitions are made that treat "8 P.M." and "20:00 hours" as equivalent expressions, while "8:00" is to be regarded exclusively (in this context) as an interpretation of the expression "8 A.M."

Of course, adopting a definition does not thereby enable one to convey something that could not also be conveyed without it. The *definiendum* can always be substituted for the *definiens*; we subscribe to each of them as if both were one and the same. What a definition allows us to do is to express ourselves more effectively in discussion; it does not enable us to say something that we could not say previously. The special merit of a definition is not that it allows us to say more, but that because a *definiendum* is much shorter than a *definiens* and because the latter contains a high level of preciseness, once having stated a definition, we can express in a few lines what

would have required many volumes. The relevance of this shorthand to the exact sciences, which are largely made up of definitions, should be obvious.

How to Precize and Define

At times it is not immediately obvious that an expression may give rise to serious misunderstanding. One reason for this might be that, over time, an expression may come to lose its preciseness. It is tremendously difficult to keep the preciseness of an expression fixed over time. Language habits change, and then we need to revise our forms of expression.

When we are told, in logic and methodology, to make our expressions precise, this very imprecise expression itself does not suggest that we should precize every expression up to the hilt, but only that our expressions should be sufficiently precise for the purposes at hand, which is quite another matter.

Excessive precization is especially undesirable because that preciseness must be bought at the cost of other desirable features of expressions, notably conciseness. It is a practical question as to where in a given situation one should leave off, and largely a matter of exercise in finding out where further precization no longer pays. Let us look at some of the considerations that might serve to prevent misplaced zeal in precizing.

First, one should consider whether taking a position on T really depends on how T is interpreted. Perhaps all the arguments that can be adduced for or against T can be equally adduced for or against any interpretation of T . In that case, it would be unnecessary to distinguish between the different interpretations, especially if the distinctions in meaning are slight.

Second, one must consider the capacity and stamina of one's audience. Generally, the stronger the precization, the greater the length and complexity of the expressions and, correspondingly, the greater the demands on the audience. Detail in itself can be an obstacle to understanding. Therefore, if we have to decide between a comparatively simple but less precise expression and one that is longer, more detailed, and more complex in construction, we must have good reasons for choosing the latter. In this situation, our choice would largely depend on the competence we attribute to our audience.

Third, the choice we make depends on how serious and frequent any misunderstandings may be. As noted before, it is impossible to eliminate *all* misunderstanding; developments in language and our own limitations in seeing what an expression implies rule that out. Serious misinterpreta-

tions must naturally be avoided, but we can often rely on the probability that interpretations will correct themselves in the course of a discussion as the audience or participants gradually come to feel comfortable with the ideas being aired. Excessive precization at the outset can easily prevent people from arriving independently at an understanding of what is being said. A person who clarifies his expressions simply to guard against their being taken in any sense other than his own may betray an unwillingness, perhaps also an inability, to see what someone else might mean by them. In the extreme case in which an expression has become resistant to reinterpretation, it is no longer a vehicle for expression but just a formula. We should precize to exclude misunderstandings we have learned to expect, not to promote the cult of univocality for its own sake. It is a matter of making this or that point somewhat clearer in order to save confusion and annoyance. For instance, a statistician who asks people their ages would save an immense amount of bother if he specifies the method of calculation he wants: whether it be age at last birthday; at next birthday; at nearest birthday; or in years; years and months; years, months, and days; and so on. But if in casual conversation someone asks our age, we do not ask what system of calculation he wants us to use.

Finally, we should remember that, for different groups of people or for different areas of discussion, the same expression *T* can stand as a shortened form of a number of different precizations. An expression about theft, for example, will tend to be precized differently by lawyers and by psychologists. Different considerations are involved. But this can easily be overlooked when we move from one group to the other, and especially when many of the words used by either group are the same. A term or expression in one field may have a high degree of preciseness; in another field, it can mean something quite different or mean the same but be unseparated from a set of precizations that are attached to it in that field. Just consider everyday, scientific, and philosophical interpretations of the expression "substance" as a case in point.

The Task and Pitfalls of Definition

As an example, I will try to arrive at a definition designed for a fixed purpose: a definition of "Christian ethics" that can be used in a debate about which religion embraces the highest moral teaching.

Begging the Question — *Petitio Principii*

When arguing about different standpoints, it is important that we can identify them. To know what we are talking about, we need to agree on a definition for each. This presupposes prior agreement about the terminology to be used. Without agreement at these two stages, fruitful discussion cannot even begin, for it will be impossible to know whether the view one criticizes is, in fact, the view one's opponent is supporting. In the case in question, then, what we need is a short statement in an agreed terminology defining "Christian ethics" for the purposes of the discussion at hand. Before undertaking a debate about the relative merits of religions, the disputants must come to some common understanding of what they are discussing.

Any definition that presupposes the superiority of a given religious moral teaching over any other will be worthless. This mistake may seem obvious; nevertheless, it is one that is frequently made, especially when the disputants are themselves representatives of the standpoints under discussion. As long as we manage to keep the evaluative component out of our definitions, discussion can proceed profitably. In the present case, we might avoid the danger of begging the question by giving a definition of "Christian ethics" in terms of the moral code enunciated in the Sermon on the Mount, for here the code is specified, not evaluated. What we must avoid are any definitions such as: (1) "Christian ethics" is taken here to mean the same as "the moral teaching that demands most of men but gives them the means to achieve the greatest happiness"; or (2) Christian ethics assumes that man will always do good toward himself and his fellows, that he will not offend against the legal code, and that he clearly understands there to be only one God. It would be absurd to base a discussion on such statements when it is precisely the question of whether a Christian moral outlook is always good that is in question.

Evading the Issue — *Circulus Vitiosus*

Our motives for defining something are clear enough. We know from experience what happens when the terms of a discussion are used by the disputants in different ways. In typical, everyday discussions, the range of possibilities is very wide. Taking our example, the question of "Christian

ethics,” people often put emphasis on the New Testament, but a quite different sense is given to the term if our definition of it is drawn, as it was frequently in the past, from the Old Testament. Similarly, one may think of Christian morality in terms of moral dogmas common to the Protestant, Roman Catholic, and Greek Orthodox churches or in terms of Lutheranism, Methodism, Anglicanism, and so on. When we want to discuss Christian ethics, we must agree on a definition. But this may well involve us in discussions on altogether different topics, for disagreement can arise over what *is* an accurate or adequate definition of “Christian ethics.”

Part of the difficulty in the present example resides in the term “ethics” and its cognates. Although we should reasonably expect a definition of the term “Christian ethics” to give some indication of how we should interpret the term “ethical,” it would be worse than useless if that was *all* it gave us, as in “To live one’s life as believers in Christ deem best.” Certainly what is “ethical” for a Christian is what that person believes to be the best way of behaving, but even if this provides a clearer notion of what ethics is, we still have not arrived at a definition of “Christian ethics.”

Consider another proposal: the Christian precepts for behavior as they are based on the example of Christ’s own life. Two distinct concepts are involved here: the proposal implies that if some precept is (1) based on Christ’s example but is not (2) a Christian precept, then it does not belong to Christian ethics. The proposer must accept this. However, he may not have intended this implication, and in such a case, he must withdraw his proposal. What he may have wanted to propose might be expressible as “those precepts that are based on Christ’s example.” In that case, the original proposal is no more than a *circular* definition, merely repeating in different words in the *definiens* what is already said or implied in the *definiendum*.

We should note that not every use of the expression “Christian” is automatically part of a circular definition. If our *definiens* is, for example, the expression “that which Mr. So-and-So calls Christian ethics,” then we have at least made a step in the right direction. The presumption is that Mr. So-and-So has specified the behavior he calls Christian, that we are willing to accept his specification for the purposes of the ensuing discussion, and that the disputants are acquainted with the specification in question. By delimiting the topic, even if only indirectly, we are beginning to be specific. We may be hedging, but we are not just beating around the bush.

Muddying the Issue—Obscurum per Obscurius

Since the purpose of a definition is to improve clarity and avoid misunderstanding, it is natural that we should look for a *definiens* among the precizations of the expression in question. But if our *definiens* of “Christian ethics” can still be interpreted in all the different ways open to the various disputants, nothing will have been gained. The matter must be clarified still further.

Although one can never hope for absolute clarity, one can at least strive to avoid the worst misunderstandings. To do this requires imagination and memory and an ability to anticipate the kinds of misunderstanding and obscurity that can arise in any given discussion group. One must be prepared for cases, as in our present example, in which (1) *A* has some misgivings about some norm that he has included under Christian and *B* either replies that this norm comes from some obscure part of the Old Testament and therefore *need* not be included under Christian ethics or that it is a Catholic norm and that, as a subscriber to Christian ethics, he does not need to be held accountable for the special dogmas of every denomination; or else that (2) *A* is talking about what Christians practice and not what they preach, and so on.

What is needed is an indication of what the Christian representative in the discussion will, *in all cases*, feel bound to support — perhaps something like the commandment about loving one’s neighbor as oneself, or some fairly clear account of a liberal or orthodox variant of Protestant-Lutheran moral teaching. What we have to try to bring out are the essential differences between Christian and other moral teachings, and for this we need a representative view of Christian teaching as a whole, irrespective of doctrinal differences.

The need for clarity and simplicity implies that the words used for the definition must be simple, ordinary, and, as much as possible, concrete. If I say that Christian ethics is “a mode of living that stipulates understanding of, and identification with, the loftiest ideals inherent in the true Christian’s standpoint,” I can hardly be thought to be laying myself open to argument. In addition to the circularity involved in the expression “true Christian standpoint,” it is unclear what ideals we are to understand and subscribe to. A better definition for purposes of argument would be something like “the morality Christ preached, centering on the positive command-

ment to love.” Here everything extraneous has been pruned away; all that is missing is a formulation of the commandment about love and a clearer idea of its relationship to the rest of Christ’s teachings. Better still would be the provision of criteria for what is to count as Christ’s teaching. The expression, “what Christ taught” may be precise for those educated in the Christian religion, but for others it may have no specific designation.

Consider the following proposal: by “ethics” I mean systems of rules for the conduct of the lives of a group of people (in this case adherents of the Christian faith). Using this proposal to precize our *definiendum*, “Christian ethics,” we obtain the following:

$T_0 \equiv$ Christian ethics.

$T_1 \equiv$ Conduct of one’s life in conformity with the Bible’s commandments.

In aligning Christian ethics with the Ten Commandments, I assume that the Commandments synthesize all of what people generally mean by “Christian ethics.” In our discussion, therefore, I believe that most of the disputants will associate Christian ethics with the Ten Commandments.

Now, although it is true that many Christians associate Christian ethics with the Ten Commandments, many non-Christians contend that the Commandments actually synthesize the content of a number of moral systems in addition to the Christian one. For them the definition would be too wide.

Consider another proposal: Christian ethics is the morality based on the Ten Commandments as they are interpreted in the Lutheran catechism. I assume here that the participants in the discussion know the Ten Commandments and the Lutheran interpretation of them. I take this definition to be sufficiently neutral, and I think it covers fairly well most of what the participants, Christian and otherwise, understand by the expression “Christian ethics.” But because I also hope to greatly limit the chances of conflicting interpretations of the expression “Christian ethics,” my proposal is also a precization of this expression.

Here we may suppose that by “participants in the discussion” the proposer means “attending members of the class of contemporary British and American theologians”; but it could be that the participants have quite different backgrounds. If so, the reference to Luther could mean too severe a restriction of the subject matter, and the definition might thus be too nar-

PRECIZATION AND DEFINITION

row. However, if the proposer is thinking in terms of a debate among Lutherans, the outcome of the discussion is too obvious to be interesting. Otherwise, the definition is fairly satisfactory, although it should really have been formulated explicitly as a *prescriptive* definition.

Sources of Error in Precization

One often hears disparaging remarks directed at those who insist on precise expression. Indeed, it is only somewhat apologetically that one resorts to the philosophical rejoinder, "It depends on what you mean by. . . ." This opening tends immediately to label one as a bore intent only on deflating the richness and profundity of the discussion, or else it is taken to be indicative of a neurotic and unsociable tendency toward hairsplitting. No doubt there is some basis for this disparagement. Precization, after all, is a means to an end, and unless there is an end, or unless it succeeds as a means, it is a waste of time. Furthermore, it is a skill, something one has to learn to become proficient. Perhaps the most common cause of failure in precization is simply lack of training. It takes a good deal of practice to be able to arrive at just the precization that the situation demands. One's precizations can miscarry because they are too long-winded or couched in inappropriate terminology, and so on. Furthermore, precization tends to be an all-or-nothing affair: success that is only partial is tantamount to failure. This perhaps accounts in part for the negative associations with demands for preciseness. We succeed too rarely to find the appropriately precise expressions for what we mean.

There is another aspect to this. We precize whenever we come across misunderstanding, and this occurs most commonly in actual debate. Unfortunately, here the conditions for doing the job properly are poor; all we can usually hope for, in the flush and flurry of debate, is some fast repair work to keep the discussion going. The real work of precization must take place when there is time for longer reflection. However, when one sits alone and recalls the issues raised in a debate, one easily forgets that the words and expressions that impress themselves on one's memory may, for the disputants, have been mere catchwords and slogans, full of sound, fury, and perhaps *some* point, but signifying much less than was initially presumed. One also tends to forget that even if the contestants are already equipped with the appropriate precizations, in the interests of persuasion, they nevertheless often

distort the views of their opponents and present them in caricature. The most important part of open debate takes place behind the scenes. One's precizations are best arrived at before the event, in an atmosphere more conducive to the collecting and sifting of arguments and information.

In inconsequential and superficial discussion, we often make attempts at precizations that lead to the replacement of an ambiguous expression by a slightly less ambiguous one. We often call this "defining." However, it is not enough just to cast around in our minds for an expression, even if it may turn out to be more precise in some ways. What is needed is the ability to recognize the source of the misunderstanding that occasions the attempt. One should be able to recognize the interpretations that constitute the misunderstanding, which requires an ability to discriminate between different groups' uses of language. Otherwise "defining" is almost certain to be a hindrance rather than a help.

One often finds precizations that end up expressing nothing of what one's original expressions were intended to convey. For example, someone versed in town planning may accept a quantitative statement about overcrowding which says that overcrowding exists when there are more than two people to a room. I, however, may be thinking of overcrowding in more qualitative terms and find that much of what I have said has to be withdrawn if interpreted anew in light of the quantitative statement.

In addition, one often finds that successful precization leads to a compartmentalization of the discussion. Instead of talking vaguely about a set of similar but not identical topics, one aspect of the set is taken and discussed at the expense of the others, which must then be dealt with separately.

One source of error, not easy to eliminate, consists of having overestimated one's ability to remember special definitions of well-established expressions. There is a natural tendency to fall back on established meanings and to resurrect the misunderstanding one sought at least temporarily to allay. Perhaps then we tend to blame the idea of precization itself instead of looking for simpler definitions or fixing them in our minds by repeating them, or simply avoiding the awkward expression altogether.

Many people seem to suppose that proper discussions must be well-attended affairs — the more the merrier — as if the typical discussion were a kind of social gathering at which everyone should have something to say. Such "discussions" can be pleasant and diverting ways of passing the time,

PRECIZATION AND DEFINITION

but as such, they are no place for precization. In such a context, precization is not only unnecessary but should be avoided because it is deliberately intended to exclude that rich variety of interpretation on which the mind must feed as it flits from one topic to another. On such occasions it would clearly be an indiscretion to ask for definitions. Nevertheless, this must not detract from the status of precization as such, for precization is an important instrument, which is essential for certain purposes. There are, of course, many situations in which either no such purposes arise or those that do arise are not served by precization.

We should also bear in mind that what people say in an idle moment is often remembered later and recast in memory as their "opinion." The more precise we are able to be generally, the less demand we create for precization, but also the less likely we are to be misrepresented when our words are later recalled and quoted. Among the innumerable activities in which precization performs no primary function are preaching and propagandizing, even though the object is to convey something by means of words. In such cases, it is much more important to create the right atmosphere for making words as compelling as possible and for heightening the audience's suggestibility than it is to speak with clarity and precision. Here, too, the demand for clear and precise utterances would be indiscreet.

New Meanings for Old Terms

One sometimes comes across the claim that two different meanings must never be expressed by the same term or terms. However, it would be extremely awkward if we had to change the term or terms every time we wanted to change a meaning. Even in the exact sciences we find changes of meaning occurring without any concomitant relinquishing of the old form of expression. Awareness of this is an essential part of understanding how knowledge develops, and it is also a prerequisite for understanding the terminology current in a given science.

Take just one example of a change of content without a corresponding change in the form of expression. The term "element" originally came to be used in chemistry in accordance with the convention that assumes that elements cannot be broken down — an assumption that radioactivity has since refuted. Radioactivity so transforms the matter that was once assumed to

comprise elements that there is no possibility of finding elements in the accepted sense. Now, there would be no scientific point in retaining an empty *concept* 'element' to which nothing answered, even though retaining the term might have some historical justification. Yet we still need a word for the matter that has all the formerly assumed properties of elements except indivisibility. Furthermore, we need a common term for iron, potassium, oxygen, and so on since these have many important characteristics in common. Because nothing falls under the old meaning of the word "element," the term becomes available for new employment. Without changing its form, we can use it to express something different from its previous meaning. The obvious course, then, is surely to retain the word "element" as the generic term for iron, potassium, and so on, but at the same time give it a new meaning, insofar as it no longer implies that elements cannot be broken down. Thus, we continue to use the old expression "element" as a descriptive term, but we use it with a different descriptive force. This procedure depends on the word's acquiring new meanings that correspond to developments in chemistry and physics and lie within the relatively indeterminate scope of everyday use of the term. Otherwise, the new usage will tend to be misleading. But if we were to change terms with every change of meaning, we would not only overtax our memories but also lose sight of the continuity in the development of science. It is partially through those very points of similarity between old and new meanings of the same word that this continuity finds its expression.

Not changing a descriptive term can be taken as a sign of such a similarity. Nevertheless, we must be clear that it is not a simple matter of choice whether we create a new term or keep the old one. A variety of factors are involved, not the least of which are the ambition and vanity of scientists themselves. History provides many examples of people who, perhaps to emphasize the originality of their own views, have introduced new terms where the old ones could have done just as well and perhaps better. On the other hand, we also see examples of how terms in a highly developed field of science are carried over to another field that is much less exact and in which the terms are then used in new but often less precise senses. Consider the term "reaction" as it is used in psychology. Borrowed from chemistry and physics, "reaction" is used with all degrees of impreciseness within the new field of inquiry. Another example is the term "function" as it is used in sociology.

Fruitful Concepts and Appropriate Terms

Old concepts are forgotten or discarded because there is no longer any use for them, and new ones emerge. But time-honored concepts can be so completely a part of our conceptual system that it may take a long time for them to be displaced by new concepts, even if the latter are more suited to contemporary modes of investigation. Language customs seldom keep pace with scientific progress.

It is also important to remember that the existence of some concept term in no way guarantees that something falls under the concept, let alone that the concept is a useful one. To explain the existence of a certain concept term, it is enough to assume that particular people once *believed* that something had the characteristics specified by the concept and that the concept at that time—under assumptions that perhaps no longer apply—was of use or at least of significance. Concepts come to be reformed as knowledge increases and errors are corrected. For instance, for a long time the view of matter as either organic or inorganic was prominent in the natural sciences. An important property of organic matter was thought to be that it could not be produced through a synthesis of simple products. But in the past century, a great number of organic materials have been produced synthetically. At the same time, the distinction between organic and inorganic has become more fluid and theories in which the distinction plays a role less widespread. The concept of organic matter has become a less fruitful one. Of the new concepts that have partially replaced the old, we can mention carbon chemistry. So-called organic chemistry is now actually carbon chemistry, the old concept term being retained in spite of the transformation of the concept.

A necessary, but by no means sufficient, condition for concept *B* to be fruitful can be formulated as follows: those things, and only those things, that fall under *B* must, in addition to properties mentioned in the conceptual description, also have other common properties of fundamental interest. However, it is not enough that a concept be fruitful. It must also have a convenient linguistic expression so that it can be used. For example, instead of “numbers only divisible by themselves and by 1,” we can use the term “prime number.” In the first place, many mathematically interesting assertions can thereby be made about numbers divisible only by themselves and by 1—that is, the concept ‘number divisible only by itself and by 1’ can be

a fruitful concept. Second, the former version is inconveniently long when constantly repeated. The same applies, if to a lesser extent, to numbers divisible by 2. For these, we have the more convenient expression “even numbers.”

It might seem that such abbreviations can hardly sustain the depth or richness of meaning necessary for our intellectual operations. But a moment's reflection makes it clear that the direction and scope of all our thinking is largely determined by what short concept terms are available. The relationship between concept terms and our thinking is in many ways similar to that between musical instruments and music. A composer develops his ability in accordance with the available possibilities for instrumentation. Thus, the broad outlines of his musical disposition are largely fixed for him, and these determine the paths taken both by creator and critic. A new instrument or a technical improvement of an old one (such as the introduction of the piano) has often opened the way to new possibilities. In the same way, the introduction of new concept terms opens the way to new possibilities for thought.

Our concept system is continually under development. To deepen our understanding of a science — whether philology, art history, mathematics, physics, or whatever — we must understand how the most important concepts in the relevant scientific discipline arose, recognize the aims they serve, and realize what changes they have undergone.

Precizing Catchphrases and Metaphors

The effect of an expression lies mainly in the thought it conveys. When someone says “It burnt to the ground” or “Democracy is outdated,” it is the alleged fact that we react to, assuming we take the expression as a genuine statement and not, as in this book, merely as an illustration of statements. It is the meaning that catches our attention — the form of the expression is ostensibly a matter of relative indifference. The force of an expression and its overall effect on an audience can, however, also depend on its form. This fact is exploited in various ways by preachers, politicians, poets, and indeed by anyone who wants to transmit something other than pure information, whether by a banal catchphrase or in the most illuminating of metaphors.

Both catchphrases and metaphors can be the products of high mental attainment. The former are usually designed specifically for their appeal

PRECIZATION AND DEFINITION

since the effect of catchphrases and slogans on their recipient's susceptibilities is a necessary part of their purpose, whether they are used in advertising or in propaganda. Metaphors, in contrast, usually arise from a person's heightened sensibility to the world of experience through language. However, as far as precization is concerned, catchphrases and metaphors both obey the same principles as do so-called literal forms of expression. Nevertheless, they are in some ways special. A metaphor can be a rich source for association and the play of fancy. An image can suggest many things to the mind, and a figurative expression can be used to convey a number of different thoughts. Metaphors, it can be said, do not *entail* impreciseness, but they invite it. It would, of course, be wrong to say that metaphorical expressions are by nature imprecise; on the contrary, a metaphorical expression may be far more precise than a "literal" one. This is again a matter of context.

However, the tendency of figurative language to foster impreciseness is something we must note. Just as we often approve of some opinion without careful consideration of our reasons, so may approval of a well-chosen metaphor stand in the way of a more exact understanding and appraisal of what is being said. A metaphor can be a means not so much of clarifying something — say, by putting some distinction in a new and telling way — but of covering up some obscurity or omission in one's thinking. Writings rich in imagery often suggest the presence of thought just below the surface, whereas the writer may not have actually progressed beyond the level of intuition in which his thoughts are still inchoate. The identification of catchphrases, slogans, and tendentious or bewildering imagery is thus essential for the prevention of uncritical and superficial thinking.

Consider the following analysis of a catchphrase. Suppose a student debating society discusses the slogan "The minority is always right" from Ibsen's *An Enemy of the People*. After much heated discussion, the ensuing division shows that the great majority are agreed that "the minority is always right." What can we propose in the way of a literal expression for a thought that can also be expressed more popularly, though less precisely, by "The minority is always right"? Here are a few possibilities:

$T_1 \equiv$ New thoughts that deserve acknowledgment generally arise
among the few and incur the opposition of the many.

$T_2 \equiv$ In social debate, the position with the weaker numerical support is generally the more tenable one.

$T_3 \equiv$ In social questions, it is generally the case that standpoints already prevalent among the plurality are less tenable than those prevalent among an especially qualified less numerous group that has as yet not succeeded in exerting its influence.

$T_4 \equiv$ The majority is seldom right when it opposes a minority that, judged according to its education, must be presumed to be competent in the given field.

As long as the student “majority” accepts some such precization, the paradox of their majority view can be resolved.

Deprecizing and Popularizing

If T_1 is a precization of T_0 , we call T_0 a “deprecization” of T_1 and the activity of finding deprecizations of a given expression, “deprecizing.” We call a presentation of a topic a “popularization” when, compared with a scientific (technical) presentation of the same topic, it requires less knowledge, a smaller vocabulary, less concentrated attention, and less depth of understanding. A popularization is not necessarily a deprecization of the technical presentation; whether it is or not depends on the circumstances. For example, if the technicalities with which a popularization is concerned are scarcely comprehensible to the public for which the popularization is made, the technical presentation can hardly be said to be less precise *for that public* than the popular version (although it might be for the initiated). In most cases, popularizations are so freely composed in relation to their corresponding technical presentations that they are generally incomparable with respect to preciseness.

For the exact study of a topic, the need for strict technical precization arises only when there is a demand for special concentration or depth of understanding. When applying the results of scientific study or presenting them to the lay public, the way the results are expressed must allow for an audience who may be unwilling or unable to concentrate for extended periods and who will probably be unfamiliar with most of the terminology. Because

PRECIZATION AND DEFINITION

of this constant shifting in our aims, we must be prepared to accommodate our presentations of a topic to the requirements of brevity in one case and technical accuracy in another. Our approach should depend on our objectives. We may have specific interpretations in mind that we are anxious to avoid, or we may be interested in producing a version suitable as a working manuscript in a research project.

When some subject matter is thought, from a technical standpoint, to be expressed satisfactorily by T_0 , the basis for this judgment lies, among other things, in the separate evaluations of several different sentences, T_1, T_2, \dots, T_n , with regard to how many and how serious the possible misunderstandings may be. The choice of expression clearly depends on a twofold consideration: avoiding both serious misunderstanding and excessive complication. For the reader, it is important to understand whether or not the subject matter is a popularized version. If it is, then the reader must realize how much of the subject matter the author glosses over or how far they have resorted to simplifying pictures or models not strictly representative of the ideas in question.

Newspaper articles on complicated topics tend to be highly popularized versions of the corresponding technical presentations. Headlines, especially, are meant to be “eye-catchers”; they are designed to grab the reader’s attention, arouse curiosity, or whet the appetite. A headline proclaiming “War cost \$1,384 billion” is designed to stop us in our tracks. The amount is sensational. Nevertheless, the statement is a severe deprecization of the article and of the sources the article draws on. Cost for *whom*? The allies? The Americans? The Axis powers and the allies? Does this include the Chinese War? Are both direct and indirect material destruction taken into account? More precise considerations will lead to difficult socioeconomic questions, which we need not delve into. A reading of the article shows us that the headline is to be understood as a deprecization of some expression such as “World War II (not including the war in China) cost \$1,384 billion in military preparations and damage to property.” Of course, quite different expressions can be popularized into the same headline, just as the expressions “The ship’s deadweight is 1,000 tons” and “The ship is 1,000 tons displacement” can have the same popularization: “The ship is a 1,000-tonner.”

III

Analytic and Synthetic Sentences

The Distinction

We can to some extent understand the way we use words as being fixed by rules of usage. In fact, our willingness to conform to rules in many ways simplifies our present discussion. In this chapter, I consider how some sentences can have their truth or falsity determined solely by means of rules of usage. For example, if an author gives a prescriptive definition of “displacement tonnage” by saying, “By a ship’s displacement tonnage I mean the weight of the water that a ship displaces when it floats,” then the following sentence *T* is true: “The greater a ship’s displacement tonnage, the greater the weight of the water it displaces.” To put it more exactly, if *T* occurs in the author’s text (given certain generally accepted rules for the use of the word *greater*), one can establish the truth of *T* without looking further. For instance, there is no need to go to the expense and effort of weighing the ship to see if *T* is true.

If the author of a text incorporating a prescriptive definition of “psychology” establishes that he is using the word in the same way as he uses the expression “the science of the self,” we can reject without further ado the sentence “Psychology is *not* the science of the self” should it appear later in the text. More exactly, if we interpret the later expression exclusively in terms of the usage rules the author has introduced, the sentence will express a false statement. We can ascertain this without carrying out any investigation into psychology. Similarly, if one person asks another, “Is it raining or not?” and the second person answers yes, this answer interpreted in a certain way is absolutely correct. The rules usually applicable to negatives imply that pairs such as “It is raining” and “It is not raining” express contradictory (mutually opposed) assertions. This again implies that

ANALYTIC AND SYNTHETIC SENTENCES

if “It is raining” is true, then “It is not raining” must be false (and vice versa). The word “or” is used in connection with the rules of disjunction, or alternation, so that “ A or B ” is true if A but not B is true and also if B but not A is true. It follows that if the rules for the words “not” and “or” are accepted, one must accept T , “It is raining or it is not raining,” as true. Meteorological observations play no part whatsoever in the truth value of T . All we need are the rules. If we cannot assume that an author follows the usual rules for “or” and “not,” then his meaning must remain unclear.

We see that once we are committed to established rules of usage, such as those found in dictionaries, we can compile a whole volume of sentences expressing truths and another of sentences expressing falsehoods with the dictionary as our only authority. These sentences, however, convey no other information than that words are used in this way rather than another. Because dictionaries are thus able to generate statements that look like ordinary factual assertions, practical difficulties can arise when expressions are formulated in unclear and, especially, original terminology. What looks like a bold, interesting statement may often be nothing but an overdressed triviality. As we have seen, many a portentous utterance turns out to be mere circumlocution or tautology.

Definitions of Analytic and Synthetic Statements (D_5). By “ X is a positive analytic statement” we shall mean the same as: “ X is true” follows from rules of usage. By “ X is a negative analytic statement” we shall mean the same as: “ X is false” follows from rules of usage.

The term “analytic” is often used as an abbreviation for “positive analytic” and “contradictory” or “self-contradictory” for “negative analytic.” The predicate “analytic” (resolving something into its parts) denotes that a truth value (a statement’s truth or falsity) is determined by resolving its expression into its component parts. The antonym of analytic is synthetic. The expression “ X is a synthetic statement” will mean here the same as the expression “ X is neither positive analytic nor negative analytic.”

To find out the truth or falsity of a *synthetic* statement, it is not enough to analyze the separate constituent parts of its meaning. Such a statement’s truth value cannot be fully established by reference only to the fixed rules of usage that its use presupposes, unless it happens to be especially *about* these

Positive analytic	Negative analytic
True synthetic	False synthetic

Figure 4. Forms of analytic and synthetic sentences.

rules. Something more is required, an investigation of some kind, a test, or some sort of observation.

Statements are only analytic or synthetic in relation to established rules of usage. Unless we can presuppose or expressly formulate some such rules, we cannot determine whether an expression is analytic or synthetic. An expression can be analytic in relation to some rules but synthetic in relation to others. The sentence “The Middle Ages ended before 1550” is analytic on the basis of the rule that says that “Middle Ages” means the same as “the period from 500 to 1550.” However, it is synthetic on the basis of the rule that says “Middle Ages” means the same as “that time in European history when Catholicism was the only form of faith.” But what shall we say of a sentence such as “I both like and dislike him”? Rephrased as “I like him and do not like him” it is clearly negative analytic on the basis of familiar rules for the words “and” and “or.” But we would hardly expect someone to deliberately infringe these rules; when we interpret the expression, we would normally reject that possibility without hesitation. The more plausible interpretation would be, “I like him in some respects and dislike him in others,” which makes it a synthetic statement (on the basis of normal English usage). Sentences such as “*U* is a precization of *T*” are synthetic expressions. They describe facts about the usage of language, facts that must be investigated when we want to test their validity. Prescriptive definitions, however, are neither analytic nor synthetic, nor are they true or false. They do not make claims about what is the case; they only propose or establish that certain pairs or groups of expressions are to be understood in the same way. Of course, insofar as prescriptive definitions *are* rules for usage, they can still be said to stand or fall as well-grounded and worthwhile prescriptions.

The different types of analytic and synthetic sentences can be illustrated as in figure 4.

Examples and Illustrations

Let us consider a few examples of the analytic/synthetic distinction.

1. *Human nature is always the same.* If we define the term “human nature” as “characteristics of humans that are always the same,” we get a positive analytic statement. If we define “human nature” so that it refers to human instincts and drives, the sentence is synthetic, assuming that we do not define “instincts” and “drives” in such a way that “always the same” enters into our definition. To arrive at a reasonably clear picture of the content of the synthetic assertion, we should precize the two vague terms “instinct” and “drive.”
2. *Pure water boils at 100° C, when the barometric pressure is 760 mm of Hg.* Because Celsius temperature is defined so that 100° C is the temperature at which pure water boils at a barometric pressure of 760 mm of Hg, the statement’s truth can be determined by means of the definition. It is therefore positive analytic.
3. *A horse is a vertebrate.* If we take the word “horse” in the zoological sense, the concept “vertebrate” enters into the definition; the statement is therefore positive analytic. However, the fact that horses are members of the class of vertebrates is not part of the definition of vertebrates. Therefore, the sentence can be interpreted as expressing a synthetic statement conveying the information that the class of vertebrates includes horses.
4. *A horse is not a vertebrate.* This is negative analytic according to example 3. Again, however, if the sentence were construed as a statement about what the class of vertebrates does not include, it could be taken as false synthetic.
5. *All horses have four legs.* This is a synthetic statement. It is a sufficiently *invariable* property of horses that they have four legs, but since a horse may be so unfortunate as to lose a leg and yet remain a horse, we cannot say that the property is part of the description of all horses, although we would still affirm that it is part of the *definition* of “horse.”

When people state some principle or assert some particularly general truth about human beings or life, they often make at least one of two as-

sumptions: (1) the utterance is an observation confirmable by experience or (2) the utterance is a positive analytic statement. Such utterances are easily confused, which often leads to their being used interchangeably. Consequently, we may feel that what someone says is undeniably true because the formal certainty of the positive analytic interpretation has become spuriously attached to what is, according to the synthetic interpretation, merely hypothetical. When asked to account for their views, defenders of such “quasi-synthetic,” “cryptoanalytic” assertions have a common tendency to retreat toward the analytic position, increasing the modesty of their assertion — and ultimately defending a mere triviality or truism. But as soon as pressure eases, they abandon caution and advance bravely in the direction of the synthetic again.

For the scientist, who is particularly concerned with making general statements that can stand up to rigorous evaluations, it is especially important to be able to recognize when a precization of an expression approaches the analytic. Since it is one of the aims of science to arrive at hypotheses that are both as general as possible and as secure as possible from disconfirmation, it would seem all too easy to arrive at generality and security by treating the statements expressing the hypotheses as analytic and, hence, unscientific. This is not to say that scientists have no use for analytic statements. They may find such statements useful, even necessary, especially where the conceptual connections between a number of new technical expressions have to be made clear. In addition, the continual striving for conceptual clarity in one’s own scientific system of thought is naturally of prime importance to the scientific researcher. He, perhaps more than any other, must become adept at distinguishing hypotheses from truisms and at spotting inconsistencies and contradictions, which is by no means an easy assignment.

To take an example, the following expressions appeared in a newspaper: “Everyone knows that a platform speech is very different from a radio talk” (T_0) and “It is something not all speakers realize” (U_0). Let us try out the following two precizations or specifications of U_0 .

$U_1 \equiv$ Not all speakers realize that everyone knows that there is a big difference between platform speeches and radio talks.

$U_2 \equiv$ Not everyone realizes that there is a big difference between platform speeches and radio talks.

T_0 and U_2 are contradictory according to the commonsense notion of contradiction, but not so T_0 and U_1 . The difference between “contradiction” in a looser and more imprecise sense and “contradiction” as a well-defined term in logic comes out clearly in the example. Technically, a contradiction between T_0 and U_1 exists only if we assume some such premise as “If everyone knows X , then all speakers know X ” (any speaker is a someone). If we accept this premise, the contradiction becomes explicit. Of course, when we use the expression “everyone knows,” we seldom mean *everyone* or even any especially large class of people. Usually we are referring to the same group in which we include ourselves as members, such as the group of “all educated and informed people.” If, as is probably the case, we are willing to concede that some speakers are not members of this group, then T_0 and U_1 are not contradictory, even from a commonsense point of view.

Expressions that approach the meaningless without actually reaching it, or that express something interesting only in a special context, play a large part in ordinary life. Take, for example, the expression “Real democracy is a just form of rule.” If we ask what definition of “real democracy” is assumed here, we will likely be told that democracy has to do with justice—in its system of voting or in the various kinds of opportunities open to individuals. In that case, we could reformulate the sentence as “Real democracy, which is a just form of rule, is a just form of rule,” which is pointless. But if all mention of justice is carefully excluded from the definition of “real democracy,” the expression may become interesting and arguable.

The same can be said for a sentence such as “It is always wrong to tell a lie.” If one person makes this claim and another brings up the case of doctors who give incorrect information to terminally ill patients, or other cases of white lies, the first person may try to oppose the objection by claiming that cases such as these are not really cases of lying: lying occurs only when one tells untruths against one’s better judgment to obtain some morally unwarranted advantage. By drawing on a special definition of “lying” that causes the original statement to convey nothing, it is possible to stand by what one has said without risk. As a further example, consider the sentence “Very high intelligence is a rare occurrence.” The expressions “high” and “low” are generally defined in relation to an average. If the apportioning of intelligence quotients follows the standard pattern for such distributions, it turns out that high intelligence *must* be rare. If an intelligence quotient of about 140 is common one year, then it will no longer be “very high” since

the average would then move in the direction of 140. Here again, whether the statement is analytic or synthetic depends on what definition one accepts when making it.

Drawing Analytic Conclusions

In this section only, I will use the word “analytic” to refer to the “drawing of conclusions” rather than the characterization of expressions. By “drawing a conclusion” I mean the transition from premises to conclusions — not the premises or conclusions themselves.

Premise P_1 : All human beings are mortal.

Premise P_2 : Smith is a human being.

Conclusion: Smith is mortal.

The conclusion emerges as a result, or product, of P_1 and P_2 .

Let us examine several additional cases.

1. Premise: The water has reached 100° C.
Conclusion: The water has reached the boiling point.
 2. Premise: Copernicus was born in 1473 and died in 1543.
Conclusion: Copernicus was born during and died after the Middle Ages.
 3. Premise: All sea serpents live in the sea.
Conclusion: There are sea serpents.
-
1. If we assume a normal definition of Celsius temperature, the conclusion is incontestable and valid.
 2. If the Middle Ages are defined as the period from 500 to 1500, this is an analytic conclusion.
 3. If we introduce a rule of usage for the word “all” such that the expression “all A ’s are B ” is only to be used if there exists at least one A , then this conclusion is also logically incontestable.

Corresponding to these three conclusions are the following three positive analytic statements (assuming the definitions already mentioned):

ANALYTIC AND SYNTHETIC SENTENCES

1. If water has reached 100° C, then it has reached the boiling point.
2. If Copernicus was born in 1473 and died in 1543, then he was born in and died after the Middle Ages.
3. If all sea serpents are in the sea, sea serpents are to be found.

Thus, the drawing of various conclusions can be formulated in conditional 'if . . . then' sentences in which the 'if' clause constitutes the premise and the 'then' clause the conclusion.

Definition of an Analytically Drawn Conclusion (D_6). The expression "X is an analytically drawn conclusion" here means the same as the expression "X is a conclusion that gives a positive analytic statement of the 'if . . . then' type with the premise as 'protasis' and the conclusion as 'apodosis'."

IV

Agreement and Disagreement

A Theory of Two Common Misunderstandings

In this chapter, I shall consider certain kinds of misunderstandings. They will probably seem rather trivial; indeed, most of them are so commonplace that it might seem that the time and space devoted to them could have been spared or better spent. However, since our purpose is to give the student a practical grasp of the theory of interpretation, we must do more than merely note and account for the various problems. The reader must become entirely familiar with them and also make the most of the opportunity to practice the techniques of avoiding misunderstandings.

When we claim to be in agreement with someone about something, our agreement is not about the expression but about what we take to be expressed. One person may say “Il neige,” another “Es schneit,” but if we agree that it is snowing, we agree with both of them. In that case, our agreement clearly depends on a prior, or implicit, agreement about how these different expressions are to be interpreted. We can declare our agreement when in fact no such agreement exists or when no such agreement is being expressed at the time. Although speaker and listener are verbally in agreement, they may not be at all agreed in substance. Often it is just that people *seem* to agree. The same goes for disagreement. These kinds of misunderstandings are no doubt very common. In any case, it is certain that a large part of our daily discourse, personal as well as political, is conducted without sufficient guarantees that the participants are really agreed or disagreed on what they believe they agree or disagree on.

Assume that person *A* utters the sentence T_0 and that by T_0 he wants to present some factual claim to person *B*. If *B* answers *A* affirmatively, we say that *A* and *B* are in *verbal agreement*; if negatively, then they are in *verbal disagreement*.

AGREEMENT AND DISAGREEMENT

For example, consider the following dialogue:

1. A: The newspaper is thin today (T_0).
2. B: Do you think so? It doesn't seem thin to me.

This is a case of what we will call “verbal” disagreement. When we say that people are in verbal agreement or disagreement, we do not imply that we have determined whether they have in fact actually agreed or disagreed, i.e., whether whatever ostensible agreement or disagreement exists is real or pseudo. We must first find out what A is affirming and B denying. Imagine that the conversation continues as follows:

3. A: But it has only six pages (T_1).
4. B: Yes, I know.
5. A: I call that thin.
6. B: Oh! So do I, but I thought you meant it was thin in news today (T_2).
7. A: No, it's not *that*.

According to (4), it appears that B has misunderstood A . According to (3), (4), and (5), it seems that the verbal disagreement at (2) was not a reliable indication of B 's attitude to what A wished to express in (1) and that he precized in (3). Statement (4) shows that A and B are agreed in substance, despite B 's declaring his disagreement with A . We can now establish the following: speaker A utters T_0 and means by T_0 the same as he means by T_1 , T_1 being a precization of T_0 . Listener B declares himself in agreement with what he believes A means by T_1 . On the assumption that A and B interpret T_1 in the same way, there exists an agreement in substance. Thus, we see that the verbal disagreement in (2) is misleading.

Definitions of Pseudo-Agreement and Pseudo-Disagreement (D_7). Listener B is in *pseudo-agreement* with speaker A if B declares himself in agreement with A when A utters T_0 , but they are really in disagreement. Listener B is in *pseudo-disagreement* with A if B declares himself in disagreement with A when A utters T_0 but they are really in agreement. Here “really in agreement” means being agreed about the truth of the assertion that the speaker has meant to express.

The ways we have for deciding what a person means by an expression are far from adequate, especially when the person himself is not available. Thus, when asserting that real agreement occurs, we should add the qualification “in light of the available evidence.” Further investigation may always bring to light new evidence that can cause us to reverse an assumption of real agreement or disagreement.

Let us now return to our example. In (5) we still do not know what *B* thought *A* meant by T_0 . For this we need (6). Up to this point, *B* has taken T_0 to be tantamount to T_2 : “The newspaper is thin in news today.” Statements (1) through (7) show that *A* and *B* are agreed about T_1 , and the emphatic “*that*” in (7) seems to show that they are also agreed about T_2 . In other words, *A* and *B* are agreed not only about what was really at issue but also about what *B* thought was at issue. Now consider another case in which the agreement about what was really at issue is pseudo-agreement:

1. *A*: The newspaper is thin today (T_0).
2. *B*: Yes, it has only six pages (T_1).
3. *A*: I meant it was thin in news today (T_2).
4. *B*: What? It has three pages of sports.

In (2) we have a verbal agreement insofar as *B* answers affirmatively to what he believes *A* means. In (3), *A* precizes his expression; then *B* does not agree with what he takes *A* to mean in this precization. Assuming *A* and *B* interpret T_2 in the same way, there is only an apparent agreement in (2). In light of the available evidence, there is no ground for assuming anything else.

Let us suppose the dialogue continues thus:

5. *A*: I meant, it's thin in political news today.
6. *B*: There I quite agree with you.

In light of (1) through (6), it would seem that there was both verbal and real agreement about T_0 in (2). More information may possibly induce us to alter even this conclusion. For us to consider the conclusion adequate, the succeeding precization must be both reasonable and strong, and such a precization is not always easy to come by.

The connection between degree of precization and risk of pseudo-agreement or pseudo-disagreement is very close. The more precise an expres-

sion is in relation to the speaker's language customs, the greater the possibility of an agreement or disagreement that is real and not only verbal. For example, when two amateurs discuss space rocketry and one of them precizes in technical terminology that would normally be used by a professional to make very precise utterances, the ensuing misunderstandings will likely be much worse than if they had kept to everyday language. In other words, the rule is that we should use a precization that is appropriate for the context at hand.

Examples of Pseudo-Agreement and Pseudo-Disagreement

1. A: The city library is bigger than the university library (T_0).
2. B: No, on the contrary.
3. A: The city library has more books than the university library (T_1).
4. B: Yes, of course, but as an architect, I am thinking about the building itself, not about the books. I thought you meant that the city library has more floor space than the university library (T_2).
5. A: But when talking about libraries, one should surely keep to the conventional way of talking about them. When talking of libraries, we naturally think in terms of books.
6. B: I think usage in this case is altogether too imprecise to permit such a decision.

Statement (4) shows there is spurious disagreement in (2) because

- a. A and B are in verbal disagreement about T_0 .
- b. By T_0 , A means T_1 and not T_2 .
- c. A and B are really agreed about T_0 .

But now consider the following exchange:

1. C: The city library is bigger than the university library (T_0).
2. D: Yes, the city library has more floor space than the university library (T_2), but it has fewer books.
3. C: There you're wrong; the city library has less floor space. I meant that the city library has more books than the university library (T_1).

Statement (2) is a case of verbal agreement, but from (3) it transpires that the agreement at (2) was actually a pseudo-agreement.

- a. *C* asserted T_1 with T_0 .
- b. *D* declared himself in agreement insofar as he interpreted T_0 as T_2 .
- c. *D* considers T_1 to be untenable.

In the following dialogue, we see an example (2) of how pseudo-agreement occurs:

- 1. *A*: Through Wergeland's action, Jews were allowed into Norway (T_0).
- 2. *B*: No, Norway has never had a law directed against Jewish people (T_1).

B's saying no shows that verbal disagreement occurs at (2). But *B*'s expression suggests that the verbal disagreement conceals real agreement. Note that *A* speaks of "Jews," and *B* of "Jewish people." The term "Jews" can be precized in a number of ways, among them the following:

- $a_0 \equiv$ Jews.
- $a_1 \equiv$ Upholders of the Mosaic Law.
- $a_2 \equiv$ Jewish people.

The precization offered by a_2 is rather weak because there are many ways to interpret the term "Jewish people"; for instance, in terms of descent or in terms of adherence to custom and law, as in a_1 . Person *B* seems to interpret *A* as saying:

$T_1 \equiv$ Through Wergeland's action, Jewish people were allowed into Norway.

However, if *A* really means something like a_1 and not what T_1 expresses, the disagreement is actually pseudo-disagreement, assuming that *B* would accept the following:

AGREEMENT AND DISAGREEMENT

$T_2 \equiv$ Through Wergeland's action, upholders of the Mosaic Law were allowed into Norway.

If A and B are well schooled in history, then B will probably assume that by "Jews" A means "upholders of the Mosaic Law." Jewish people of the Evangelical Lutheran faith were allowed into Norway before Wergeland's action.

The following shows an example of confusion between a pseudo-agreement and a difference in interpretation:

1. A : Wergeland obtained entry into Norway for Jews.
2. B : I know.
3. A : By "Jews" I mean people of Jewish descent.
4. B : Oh! I understood you to mean upholders of the Mosaic Law.

Statements (3) and (4) show that A and B had different concepts of 'Jew' in mind. Of course, this is not enough to show that there is pseudo-agreement. For that, we need to know how B views A 's interpretation of (1).

Below is an example of conflation of pseudo-agreement and disagreement about something other than T_0 :

1. A : The United States deservedly beat England in New York yesterday.
2. B : Yes, the American center forward was dazzling.
3. A : No, I didn't mean that. The American team seemed to me better all around; no single player was particularly outstanding.
4. B : I don't agree.

Statements (1) through (4) are not susceptible to any precization that could result in a demonstration of pseudo-agreement. Statements (3) and (4) show that A and B are really disagreed about the American center forward, but this is not enough to enable us to decide whether it is also a case of pseudo-agreement about T_0 , contrary to what one might unreflectively suppose.

Our interpretations of one another's expressions tend to exhibit deviations that vary according to the uncertainties in our language. However, this in itself does not necessarily lead to pseudo-agreement or pseudo-disagreement. If we use an expression to assert something and the expres-

sion lends itself to several reasonable precisizations, we would often accept the truth of all or most of these precisizations. If by T_0 we only affirm the truth of T_1 , this does not exclude the possibility of our also affirming the truth of T_2 , T_3 , and so on.

Applications of the Theory

Pseudo-disagreement often arises when we are familiar with only *one* established authority and we have neglected to check our assertions with other authorities. Suppose *A* reads in a geology textbook that there were three Ice Ages in the Pleistocene epoch, whereas *B* reads in a similar work that there were eleven. Both *A* and *B* might reasonably conjecture that geologists are disagreed and that their disagreement is more than just verbal. However, they would in fact be wrong to assume that the term “Ice Age” stands for only one concept shared by all geologists. The number of Ice Ages tends to differ from one expert to another. The disagreement can be pseudo-disagreement. Some geologists argue that each Ice Age includes several “more or less significant forward thrusts and subsequent spasmodic withdrawals of ice.” Thus, it becomes only a question of words whether we count a forward thrust as an Ice Age in itself or only as a spasm in another Ice Age. This is chiefly what causes the number of Ice Ages to vary as much as it does among scientists. However, there is less disagreement about the facts, and it is generally agreed that there have been at least three major Ice Ages.

Nevertheless, one would think that there should be no real call for terminological disagreement among scientists. It should require little effort on their part to keep up to date with one another’s terminology. We do not expect scientists to maintain statements of the kind “There have been x Ice Ages,” in which x varies from three to eleven. Rather their claims are of the form “There have been x Ice Ages,” in which it is assumed that the term “Ice Age” means such and such (y). When y varies, x also varies. Once this is made clear, we can see where the disagreements lie.

Popularization of science, indeed any attempt to transmit scientific ideas beyond an immediate scientific circle, tends to invite pseudo-disagreement. The words used in popularizing some idea or concept must be borrowed largely from a vocabulary built on relatively chance associations—not one that has evolved rationally. The potential for attaining a high

AGREEMENT AND DISAGREEMENT

depth of understanding of the ideas or concepts must inevitably be lower for the lay public than it is for trained specialists. From this, of course, we do not conclude that popularizing is an evil, but only that readers of popular versions should be aware of the special pitfalls.

It would be rash to assume generally that disputants have an unconditional desire to avoid pseudo-agreement and disagreement. On the contrary, other considerations may cut across the need for consistency and agreement, such as the requirements for persuasion. We say of two people who support one another in a debate that they are "on the same side." However, it is often necessary to present the standpoint of the side in such a way as to make it especially clear that its adherents are in fact on one side and in opposition to the standpoint of another side. Any differences among the supporters of one side must not be allowed to come into the open; the supporters of that side must seek a common platform and target.

The main considerations in social or political organizing are those of unification and activation of the group or side. As often as not, what is needed is deprecization of the expressions of the party aims because the points on which members of the supporting group differ among themselves will have to be omitted or transcended to avoid division or splits within the group itself. Here we can readily appreciate the usefulness of catchwords and slogans for those interested in maintaining party solidarity. The use of eulogisms and dyslogisms (expressions with strong positive and strong negative emotional emphasis, respectively) tends to affect the intelligibility of a standpoint, even among its own supporters—a fact that can be exploited to produce deliberately inculcated pseudo-agreement within the group. For purposes of unification, pseudo-agreement can be as effective as real agreement. A clever party organizer keeps a watchful eye on internal differences in order to repair the expressions of the party aims in such a way that they continue to gloss over such disagreement.

In addition to this, the party or side must confront its opposition with as powerful a position as it can muster. For this, the spokesperson or organizer tries to make the differences between the opposing sides or parties appear as deep as possible, thereby making the conflict more clear-cut. This most likely requires gross simplification of the opponent's view. Adolf Hitler argued that part of a great leader's genius is the ability to make opponents of very different kinds appear as if they belong to the same category. This principle applies in every sort of dispute, whether it is a politi-

cal or a family one: there must be no doubt which side you are on, hence you must avoid touching on any points on which the opposing groups may agree, and reinforce all those on which they are known to disagree. The end result is an extensive illusion of disagreement.

The exposure of spurious agreements becomes increasingly dangerous to a group when its members are unable to combine energetic action with a critical analytic attitude. In fact, if the group's members were better trained in these respects, there would be less need to achieve the group's aim by resorting to pseudo-agreement or pseudo-disagreement. Of course, conscious use of such methods is a form of deceit.

The French philosopher Le Bon (1931) conducted an investigation, directed mainly at politicians, that was designed to produce a clear survey of the different possible precizations of "democracy." Some of the results he obtained can be used to illustrate several points in our discussion. Le Bon was not looking for evaluations of democracy, but for precizations of the term "democracy." However, since politicians are leaders of groups or nations, and since they must be expected to further the interests of the people they represent, the answers they offer will probably reflect the aims of their constituency more than an arbitrary questioner's. The answers Le Bon received confirm this assumption.

Let us consider the answers given by Herriot (a democrat) and Mussolini (a fascist). Herriot said, "Democracy is the policy of government that tries to bring morality and politics closer to one another until they coincide" (translated from Le Bon 1931: 290–301). We can add to this another of Herriot's formulations to make his meaning clearer: "Democracy is the form of government which tries to establish that view of justice which comes not from nature, but from reason" (ibid.). Instead of describing a form of government, Herriot gives a distant *aim* that democrats try to realize with the help of the democratic form of government. The aim in question is one that most people, whether democratically or undemocratically inclined, will find almost impossible to reject. It then seems an obvious conclusion that one must also accept the stated *means* of acquiring the aim, that is, a democratic form of government, especially when one learns that "democracy" designates precisely the form of government that serves the accepted purpose. Thus, Herriot's way of expression is well suited to eliciting a positive attitude, not just to the word "democracy," but also to those who claim to be democrats. Furthermore, by bringing in the term "moral-

ity," Herriot manages to make it almost impossible to reject democracy, for people generally read into this term precisely the morality that they themselves subscribe to. Thus, two people holding different and to some extent incompatible moral norms may nevertheless justifiably claim to be democratic in Herriot's sense. However, what Herriot most likely meant to say was that democracy is that form of government that tries to bring politics into line with *his* own notion of morality (a variation of Christian and humanist morality). By slurring over this crucial detail in his specification of democracy, Herriot may attract support, but undoubtedly a great deal of it will consist of pseudo-agreement with his actual views.

Mussolini's answer to the question was, "Democracy is the form of government which gives, or tries to give, the people the illusion of their own sovereignty" (translated from Le Bon 1931: 291). As in Herriot's answer, this contains a statement of the alleged aims or desired effect of a system of government with no indication of what that system of government is, except that it is designed to promote those aims and have those effects. In general, the more neutral way of characterizing a form of government is to describe the way it functions, not what its proponents or opponents claim it will achieve. The important differences between political systems exist much less in the ultimate aims they profess than in the policies they form in pursuit of more immediate ends. By identifying ultimate aims and policies, we seem to impart to the former the disagreement that belongs more correctly to the latter. As a catchword, "democracy" can have either a strongly positive or a strongly negative emotional force depending on one's selection among the range of such notorious indeterminables as "ultimate" purposes and "real" motives. In either case, there is nearly always something plausible about the resulting description of democracy, so that one's attitude is, as required, easily swayed in one direction or the other. Whatever political viewpoint one holds, the view Mussolini calls "democracy" will generally be objectionable. By describing democracy in these pejorative terms and implying that they adequately characterize the view held by his opponents, he manages to create an effective political platform, but he does so by producing the illusion of disagreement.

In conclusion, the reader might consider whether he takes the following to be a fairly neutral definition of the democratic form of government: "It is a form of government in which the rule of the state is legally bound to the individual members of the body politic as a whole."

Pseudo-Agreement in Argument

Often a given expression can express a number of different assertions, some of them easy to argue for but uninteresting, and others that, if they were true, would be of considerable interest but which, in fact, cannot be argued for or justified (see chapter 5, pp. 84–95 on tenability and relevance in argument). It is then tempting to argue for the exciting but unconfirmable assertion by conflating it with the dull but confirmable one. We can argue for U by asserting T , and for V by asserting U , but either we obscure, or fail to see, that in the first stage of the argument we have given U the sense of U_1 and in the second stage we have given U the sense of U_2 , although T may not be a valid argument for U_2 , nor U_1 a valid argument for V . The falsity of such conclusions can be rendered schematically below:

1. U because T
 V because U
2. U_1 because T
 V because U_2

In (1) U is not precized, and we arrive at the conclusion V on the basis of T and U . In (2), however, U is precized and the two parts are seen to be logically disconnected.

The relationship between pseudo-agreement and this kind of mistake is especially clear when we consider the thoughts not of two people but of one. Instead of the thoughts and judgments of different people, A and B , we have simply the different thoughts or judgments, A and B , of one person, P . In judgment A , person P adopts the U_1 sense of expression U , while in judgment B , he adopts the U_2 sense. The resulting pseudo-agreement between judgments A and B is one that people commonly make, especially when arguing for a standpoint under certain explicit reservations. Those reservations may be made explicit by means of a precization, U_1 , but later on be forgotten or lost sight of and a conclusion arrived at from the unqualified U , which would not at all follow from the precization U_1 . We can illustrate this with a simple example:

$T \equiv$ Water has a specific gravity of 1.

$U \equiv$ The water in Oslo Fjord has a specific gravity of 1.

AGREEMENT AND DISAGREEMENT

$V \equiv$ Anything that has a specific gravity of more than 1 will sink in Oslo Fjord.

In U we have to assume that “water” means ‘chemically pure’ water; otherwise U cannot be justified by T , in which “water” does stand for ‘chemically pure’ water. We can then precize as follows:

$U_1 \equiv$ Chemically pure water in Oslo Fjord has a specific gravity of 1.

$U_2 \equiv$ Seawater in Oslo Fjord has a specific gravity of 1.

Of course, U_2 is invalid because the specific gravity of seawater is greater than 1; hence, some things will float in Oslo Fjord even if their specific gravity exceeds 1.

Imprecise pronouncements are often made with an air of great conviction, yet without the support of any argument. If those who make them are subjected to criticism, they frequently fall back on the face-saving tactic of saying that the criticism implies more in their original expression than they intended by it. They might argue, “There were qualifications that were assumed, of course; I would not be so bold as to claim. . . .” Imagine a situation in which A asserts T_0 , which can be sensibly precized in the direction of T_1 . Person B , taking A to *mean* T_1 , declares himself in disagreement and puts forward a counterargument. Then A says that B has misunderstood him and that they are probably only in apparent disagreement; he only meant T_2 . So the discussion ends.

In a case in which the strong but unjustifiable argument expressed in T_1 can be used by A to support his cause, A will probably, and wisely, prefer to use the less precise T_0 and keep the trivial but justifiable argument expressed in T_2 as a backup in case he meets a critic. If person A does encounter criticism, he then has no need to retract anything and can always claim to be less bold than the critic supposes.

Surveys of Arguments for and Against a Standpoint

Psychological and Philosophical Background

Before deciding on any difficult course of action, we normally weigh the various considerations that we take to be relevant and base our decision on an estimate of their relative importance. The same approach can be applied to any arguable issue. Arguments are appeals to rationality in light of the facts. In the following, I shall mean by “argument” the element of our expressions that carries the power to convince people in rational discussion, that is, their factual content and consequences.

One can weigh arguments for and against something immediately before coming to a conclusion by reviewing all the relevant considerations made up to that point. It is more common, however, for arguments to acquire their force or weight over a period of time. This is usually what happens, for instance, when people vote at elections. Few of us actually make a survey of the arguments that have led us to the opinions we hold when we cast our vote. If we are suddenly asked what arguments we have used to arrive at our present decision to vote for a certain party, the inadequacy of our answers will often surprise us. We may find that the feeling of certainty and confidence we have about the rightness of our opinions is not borne out by the arguments we are able to produce in their favor.

In this chapter, I will give examples of “surveys” of arguments for and against a standpoint or a decision. Sometimes because of the complexity of particular decision problems, it will be impossible to give a full survey of the relevant arguments. But remember, completeness in itself is not a necessity. If we already understand the background of a certain decision and the decision is one with which we disagree, we need only concentrate on those phases of the argument in which the differences arise. It is often sufficient to distinguish the main outlines of an argument without going into all the details.

We must first distinguish between reason (*ratio*) and motivation (*causa*), that is, between what speaks in favor of a standpoint (pro argument) and the psychological, sociological, and other causal factors that motivate a decision. Our reasons can be valid or invalid (cognitively adequate or inadequate), but our motivations merely *operate* on our actions or decisions. Generally, our motivations cannot be described as valid or invalid. A person may give as a reason for his leaving for Madrid in January that he wants to feel the warmth of the sun. As an argument, the reason is scarcely valid because in January it is usually rather cold in Madrid. But the reason given may not be identical with the motivation. What motivates the projected visit may be a strong inclination to travel, and this is something that is neither valid nor invalid.

Psychology teaches us that the motives of our actions are in varying degrees concealed from us, that many of our avowed motives are what the psychologist calls "rationalizations." In general, we will maintain that a belief in the validity of certain arguments is partially, if not wholly, the motive for our deciding as we do. But if there is no connection between our reasons and our motives, the justification we give is at best misleading. Many of the considerations that we believe arise from our own free will are seen in retrospect as attempts to find arguments in favor of a conclusion we have already reached. However conscious we are of our own motives, we must always allow for the psychological fact that in accepting a conclusion, well-grounded or not, we deprive ourselves to some extent of the capacity to entertain counter arguments. The security of a position, the pleasure even, of being convinced about something is sometimes bought at the expense of blindness to possible refutations. We should therefore try to spend more of our energies on pursuing counter arguments than on looking for fresh pro arguments for some previously arrived-at conclusion. We have to reverse the normal selective habits of our minds, a mental tendency that, in this case, weakens the rationality of our views and, hence, their acceptability in serious debate.

If we base an important action on a conclusion arrived at by argument and it is against our own interests to reject that conclusion, we may simply lose interest in counter arguments. But we may go further, to the point at which we are in danger of declaring that anyone who holds an opposing view must be intellectually, even morally, subnormal. This distressing tendency can be prevented if, in establishing our own conclusions, we always test our views according to the most qualified criteria available. An added

advantage of this procedure is that by evaluating possible objections to our own views, we are better prepared to criticize objections that might be brought against them.

Intellectual honesty can, of course, go against the grain of personal desires and interests. The more we acknowledge the force of counter arguments, the greater the perseverance, energy, and willpower needed to act according to reason rather than inclination or interests. Acknowledging the reasonableness of an objection to one's proposed course of action can easily lead to doubt and then to hesitancy. Whether one acts from principle or simply from inclination, the prompt and effective accomplishment of one's purposes may therefore depend on the ability to turn a blind eye to counter arguments.

The ability to envisage arguments for and against a course of action is often subject to mistrust. It is said that people who are always analyzing proposed courses of action dissipate their energy and find themselves paralyzed, insofar as they can always find as many reasons for not doing something as they can for doing it.

Perhaps reason *can* be a stultifier; certainly it is a ready source of excuses. Unless allied with our capacity to judge the relative merits of arguments for and against something, reason is easily misused. But that does not mean that we should avoid looking for arguments, and in particular for counter arguments. Yet someone who is completely convinced that his own plan of action is the only proper one may find it difficult to consider arguments for rejecting this plan when expediency urges him to act otherwise. In justifying this action, he must leave a great deal to chance.

Sensitivity to the reasons for actions is often felt to be incompatible with the effective fulfillment of responsibility and the single-minded devotion to one's ideals. Thus, intellectual clarity in the weighing of considerations comes to be looked on as a sign of cynicism and lack of conscience. Furthermore, every time a counter argument is ignored, the premises on which a decision to act is based become that much more simplified. Yet it should be clear that the more we are able to act consistently and unhesitatingly on the basis of complicated premises, the less need there is to distort these premises when it becomes necessary to justify our decisions.

Most of what I have discussed here also applies to taking positions on issues not directly related to choices of action. In understanding theoretical standpoints, it is also important to be able to detect counter arguments that

SURVEYS OF ARGUMENTS FOR AND AGAINST A STANDPOINT

are superficially expressed or even completely hidden in order to see whether the path to the conclusion is as clear-cut and straight as the beguiling expressions suggest.

The habit of looking at a question from all possible angles and of reviewing all relevant pro and con arguments plays an important role in intelligent behavior. Since circumstances are liable to undergo significant changes, one must be on the lookout for corresponding shifts in emphasis and for the existence of new arguments. The less we review the considerations governing our decision making, the greater the risk that we will continue to act according to an earlier decision when some new fact makes it unintelligent for us to do so. Any self-confidence and effectiveness we may gain by selective vision and intellectually indefensible treatment of the counter arguments only makes matters worse whenever fresh considerations arise. Applying this principle to politics, for example, it seems that the acceptance of a position on the basis of a pro and con evaluation would serve to strengthen the tendency toward a peaceful wielding of power, whereas a reluctance to entertain counterarguments could reinforce an unciliatory and vengeful frame of mind with all its grim consequences.

Pro et contra dicere (to speak for and against) can be understood as a special method of thinking. It is a method that falls exactly in line with the working principles of scientific research, and it characterizes the scientific attitude toward questions that cannot be definitely answered in the way that is possible in the exact sciences. In ancient Greece, there lived a great thinker, Carneades (c. 214–129 B.C.), who placed method at the center of his philosophy. Carneades accepted no standpoint as absolutely certain: one could always find something to say against a given position. So, too, with the alleged falsity of a given standpoint, one could always find *something* to say in its favor. Carneades was bold enough to argue for and against everything, despite the ill will he thereby drew upon himself. He also believed that one could act promptly and effectively, merely by considering some standpoint more *probable* than others. He considered absolute certainty to be as unnecessary as it was unattainable.

Whether or not Carneades was right, we can raise the objection, from a psychological standpoint, that with the limited resources of intelligence and effectiveness we are able to draw on, we do run a great risk of misusing the *pro* and *contra* method of arguing. We must therefore be attentive to the possible pitfalls.

One such pitfall occurs when, in reviewing a complicated string of arguments for and against the matter in question, we tend to normalize the weight attached to each argument so that when aggregating, the strong arguments grow weaker, and the weaker ones stronger. Even when a decision involves complex argumentation, it may be that only a few simple steps in the chain are the conclusive ones. The spreading of the load, then, can mean that we lose sight of the essentials. As I have remarked before, reason must be allied to a capacity to judge the relative merits of arguments for and against something. Practice is needed to sustain the alliance. One must accustom oneself to the thought that some arguments are more pertinent or more conclusive than others, while remembering that none are entirely without significance.

Pro et Contra and Pro aut Contra

Let us distinguish between two forms of surveying arguments: those that are *pro et contra* (for *and* against) and those that are *pro aut contra* (for *or* against).

A *pro et contra* survey is a straightforward survey of (1) the most important arguments that, in a given field of discussion, are or will most likely be adduced *in favor* of an assertion *and* (2) the most important arguments that, in the same area of discussion, are or will most likely be adduced *against* the same assertion. This type of survey contains no conclusion. The separate arguments are never weighed against one another. The object is merely to set out the arguments as though they were intended for an outside observer of the discussion. In practice, of course, there is usually too little time to ascertain all the arguments that have been or could be made both for and against an assertion; thus, fully satisfying requirements of (1) and (2) is usually impracticable. We must then be content with noting down whatever arguments we can remember or think of with regard to the discussion.

A *pro aut contra* survey is one with a conclusion. It consists of the most important arguments that, according to the surveyor or some person or group, have been or will likely be adduced for *or* against an assertion. A survey of this type ends in a conclusion and implies, accordingly, that the arguments have all been weighed against one another. We will assume here that the *pro aut contra* surveyor considers the conclusion to be adequately derived from the arguments in its favor.

SURVEYS OF ARGUMENTS FOR AND AGAINST A STANDPOINT

All *pro et* and *pro aut contra* surveys are preceded by a reasonably precise expression of the statement that is being argued. This is the expression of the issue, or the “issue expression,” which we will designate F_0 . Both types of surveys lay out the arguments themselves, but the *pro aut contra* survey also adds a conclusion.

A *pro aut contra* survey should contain no contradictions; in particular (1) no argument should arise both as a *pro* argument and as a *contra* argument, (2) all the arguments should be compatible with one another, and (3) no assertion should implicitly or explicitly be both accepted and rejected. Requirement (3) can be understood as a special case of requirement (2).

The following caricature of a *pro aut contra* survey illustrates the importance of compatibility. Suppose Mr. A’s lawyer draws up a survey:

$F_0 \equiv$ A is bound to compensate B for the dog-eared book.

$C_1 \equiv$ A has never borrowed any book from B.

$C_2 \equiv$ The book belongs to A, not to B.

$C_3 \equiv$ A has already returned the book to B intact.

$C_4 \equiv$ The book was already dog-eared before A got it to B.

The various *contra* arguments here are not all compatible with one another. Statements C_1 and C_4 are incompatible, as are C_1 and C_3 , at least if we assume that A cannot have given the book back to B without having *borrowed* it (which is not necessarily the case). To accept C_1 thus means to reject C_3 and C_4 and vice versa. We can also note that C_1 and C_4 infringe requirement (3) that no assertion should implicitly or explicitly be both accepted and rejected, since the assertion that A has borrowed a book from B is explicitly rejected in C_1 and implicitly accepted in C_4 . This *pro aut contra* survey can therefore be rejected out of hand. However, there is nothing to prevent C_1 through C_4 from being included in a *pro et contra* survey. *Pro et contra* surveys are not restricted to one person; they can contain the actual or possible arguments of a number of different people, even over a long period of time. In a *pro et contra* survey, it is reasonable for the same assertion to be both accepted and rejected; an assertion and its negation can both appear as arguments.

Suppose some people support a reform because they consider that it will strengthen the country’s economy, while others oppose it because they consider it will not. The argument “The reform will strengthen the coun-

try's economy" can occur as a pro argument and the argument "The reform will not strengthen the country's economy" as a contra argument. Even when a *pro et contra* survey contains the arguments of only one person, it may still contain contradictions, which are especially likely to arise when the arguments emerge at intervals over a long period of time. Naturally, however, our expectation for contradictions is lower for the single person case than for the multiple persons case.

In *pro et contra* surveys, one may also find arguments occurring both as pro and as contra arguments. Some people, for instance, have recommended that a university syllabus not include compulsory courses. One of the primary arguments is based on the assumption that not having to take certain classes makes it easier for students to work at places other than the university (T_0). Others, however, see it as an advantage for students to be required to attend the university. The latter then use T_0 as a contra argument. Here one must enter T_0 in both columns of a *pro et contra* list.

Issue Expressions

It is best if the statement of an issue being argued can be expressed in one sentence. If the issue expression consists of more than one sentence, we must be clear that together the sentences express one unified statement. If the claim can be divided into more than one statement, it is possible that the arguments can no longer be adequately classified as pro or contra since one and the same argument may be a pro argument in relation to one part of the claim and a contra argument (or even irrelevant) in relation to another. In the following, unless expressly stated otherwise, we assume that whatever is at issue can be expressed in one sentence, which is designated as F_0 .

When it is difficult to give an exact expression to an assertion in just one sentence, it may be expedient to make the issue expression as compendious as possible, even at the expense of preciseness. All that is necessary then is to add a comment to the issue expression indicating a strong precization of F_0 that is to be taken as meaning the same as F_0 throughout the subsequent discussion or survey. Further comments may also be needed; whether or not they are needed becomes clear as soon as a debate gets under way. The same goes for questions about how strongly F_0 should be precized. Here we can apply the rule that one's precizations should not be so strong as

to bring out shades and distinctions of meaning that have no bearing on the issue being raised and that do not affect the arguments in any way.

When trying to decide something, we seldom consider only one possible conclusion. We are normally prepared to consider a number of practical possibilities, such as when we are choosing a course to fulfill a school's language requirements. If the school requires two languages, we do not choose between French and not-French, but among French, Spanish, German, and so forth. Because the number of offerings is limited, there is no need to consider arguments that apply to all possible combinations as there would be if the choice were between any two or none at all. If we have already agreed to accept one of a range of alternatives, we can save time by mentioning what the possible alternatives to F_0 are.

Often a quick decision is needed. In that case, a comprehensive *pro et contra* survey is too time consuming to be useful, unless it has been prepared beforehand. It is, of course, a wise step as well as an exercise in intelligence to anticipate both the situations in which decisions are needed and the considerations that might bear on them. In this way, we prepare ourselves to act from prearranged dispositions to this or that decision in this or that kind of situation. When one then encounters an actual situation, one can ask oneself what set of matching conditions appropriate in this *sort* of situation are to apply in the present case. The good chess player, we all know, thinks a number of possible moves ahead.

Argument Expressions

It often pays to make a *pro et contra* survey before beginning a *pro aut contra* survey on the same issue. In a practical sense, the requirement of the first survey is to glean an all-around knowledge of the considerations adduced in the course of the discussion by adherents and opponents of the standpoint being contested. One should also include arguments that one considers to be untenable or irrelevant if these have been introduced in the discussion. Whether such arguments come into *pro et contra* surveys depends only on whether one of the disputants views it as a compelling argument. The requirement of the second survey is to evaluate the arguments critically and then arrive at a revised survey of the arguments that presents a particular position.

Arguments that directly bear out an issue expression are called *pro arguments of the first order*. These are numbered in the following way: $P_1, P_2,$

\dots, P_n . Similarly, contra arguments of the first order are designated C_1, C_2, \dots, C_n . Every argument should be formulated so that one can see clearly whether it is consistent with both the issue expression and the remaining arguments in the list.

It may happen that an argument of the first order can itself become an issue expression in a new survey. Such a survey can be grafted onto the original list in the way illustrated in figure 5. Arguments for and against an argument of the first order are called arguments of the second order relative to F_0 . Arguments that support a pro argument of the first order are called *pro-pro arguments*; those that rebut a pro argument of the first order are *contra-pro arguments*. Any arguments of the higher order that become an issue must themselves be made the object of *pro et contra* surveys, and so on.

That one reaches a final link in the chain of arguments is because there is a stage when an issue comes to be treated, if not as “unquestionable” (in the sense of “conclusive”), then in a more restricted sense as “not questioned” in the scope of the given discussion. We must also make some qualifying statements about the questioner. He must be considered competent. But we should be cautious here; if a person’s competence is in question, it may be wise to include an assertion about this in the *pro et contra* list. It is unwise to succumb to the temptation of assuming that one’s opponent is ipso facto incompetent.

The most important condition for bringing a discussion or a survey to a conclusion is that it have a definite aim. There must be an accepted end to it; often a schematic review of the arguments will suffice to clear up the point discussed. The main consideration is that the survey give a clear and complete account of the crucial arguments relevant to the given discussion. It is a common mistake in the presentation of arguments of a higher order to include irrelevant arguments that tend to obscure the force of the relevant ones. Differences of opinion often appear to be complete, but closer analysis often shows that the different standpoints can be traced to controversies over minor and comparatively few points. The balance can often be accounted for by a disposition to aggressiveness and other forms of self-assertion, or perhaps simply to lack of knowledge of one’s opponent.

The structure of an argument can be set up in a number of ways. One of them is shown in figure 5. The argument symbols should be read from left to right. Thus, “ $P_1P_2C_1$ ” is to be read as “pro argument no. 1 for pro argument no. 2 for contra argument no. 1 (against F_0).”

SURVEYS OF ARGUMENTS FOR AND AGAINST A STANDPOINT

Figure 5. Schematic of the structure of an argument.

According to the kind and number of arguments of higher orders, one can find different ways of making satisfactory surveys. The following examples demonstrate a variety of organizing frameworks. The important thing is that a survey should show clearly how each sentence is related to the others in the pattern of the argumentation, which can sometimes be a very difficult thing to accomplish.

Tenability and Relevance of Arguments

To be able to use a *pro et contra* list to determine one's own position with respect to some F_0 , one must judge each argument, pro and con, separately and then weigh them against one another. We must first select from the *pro et contra* list those arguments that we consider to be the most important and organize them by how we think they are related to one another. In deciding whether some argument ought to be included in such a survey, it is no use demanding merely that it should have *either* some relevance *or* some tenability. Both characteristics are needed. Then we weigh pro arguments against contra arguments and eventually come to a conclusion. It is only then that we first get a complete *pro aut contra* list. The final assessment or conclusion should be expressed briefly and should contain no arguments itself.

We must pay attention to two things when weighing the pros and cons of an argument. First, we must ask ourselves how sure we can be that the

argument is a tenable assertion in itself. Second, we must ask ourselves how strongly the argument speaks for or against F_0 . In other words, how great is its proof potential or, simply, how relevant is it?

The greater an argument's relevance, the less certain we may be about its tenability as an assertion for it to be included in our list. For example, if there is a probability of only 1 in 1,000 that a thunderbolt will strike the place where I am standing within the next few minutes, I am still justified in including the assertion "A thunderbolt may strike here at any moment" among the contra arguments relative to the issue expression "We must stand here to get a good view." However, if an assertion has a high degree of probability in itself, we may be justified in noting it even if its relevance is slight.

When deciding whether an argument is tenable or not, it often pays to consider what we would have to do to find out whether or not it is true. It is likely the case that the necessary investigations have not been carried out for a great number of arguments.

The procedure for determining the degree of relevance of an argument is rather different. The decision is ultimately intuitive; one can only "feel" that the argument should or should not appear in a *pro aut contra* list. Appeal to intuition does not necessarily render the decision less certain. At a more advanced stage, one might be able to replace the intuitive decision with something less intuitive and more rational, something in the way of an explanation. However, it would be vain to suppose that we can avoid every appeal to intuition.

The demand for relevance varies according to whether the issue expression states that something *is* such and such (descriptive F_0) or that something *should be* such and such (normative F_0). For a descriptive F_0 , the relevance of T increases in step with our belief that the truth of argument T implies the truth of F_0 . For a normative F_0 , the relevance of P increases in step with the value of pro argument P (or the more beneficial it is that P be realized). This rule also applies when P is an assertion about what follows from accepting F_0 or from behaving as F_0 prescribes. For a normative F_0 , the relevance of C increases in step with the negative value of contra argument C (or the more unfortunate it would be if C were to be realized).

When evaluating the *tenability* of arguments in relation to a descriptive issue expression, one simply asks, "How likely is it that the assertions con-

stituting pro argument P_1 and contra argument C_1 are true?" In contrast, when evaluating the *relevance* of arguments, one asks, "How likely is it that if P_1 is true then F_0 is true, and how probable is it that if C_1 is true then not- F_0 is true (F_0 is false)?" When evaluating the tenability of arguments in relation to a normative issue, one must distinguish between arguments stating norms and arguments stating probable consequences. In the former case, one should ask, "Do I find this norm tenable?," or "Would I choose this rather than alternative norms?" In the latter case, one should ask, "Is it the case, as the argument states, that such and such consequences will result from my decision?" When evaluating the relevance of these arguments, in the former case, one should ask, "If I acknowledge the norm stated in the argument, does it then follow that I ought to do what is implied by F_0 ?" In the latter case, one should ask, "If I acknowledge that such and such will be the most probable consequences of my action, shall I then choose this action?" The following examples may enable the reader to grasp these rules and distinctions more readily.

The first two simple examples bring out the factors of validity and relevance.

Example 1

$F_0 \equiv$ It will rain tonight.

$P_1 \equiv$ The sky is covered with gray clouds.

$P_2 \equiv$ The swallows are flying low.

$C_1 \equiv$ The barometer is rising.

We may take all three arguments to have a relatively high degree of *validity*, especially P_1 and C_1 , because they are based on trustworthy observations. The relevance of P_1 and P_2 are of the same order as the probability of the hypothesis that, if the sky is covered with gray clouds and swallows fly low, it will rain in the night. The relevance of C_1 is of the same order as the probability of the hypothesis that, if the barometer rises, it will not rain in the night. If we intuitively accept the likelihood of the first hypothesis, we will accept the conclusion that it will rain tonight rather than its negation. But the *relevance* of the pro arguments, especially P_2 , seems so slight that we must consider the conclusion to be extremely uncertain.

Example 2

For a very simple example of a *pro aut contra* survey with a normative issue expression, consider this familiar kind of story. Peter was studying for his degree in mathematics. He was so interested in his work that he could not consider devoting his working hours to anything but pursuing his studies. But he enjoyed reading poetry, of the kind one cannot enjoyably read when one is tired. To clarify his problem, Peter set up a small *pro aut contra* list:

$F_0 \equiv$ As long as I study, I have to devote all my time to my subject.

Antithesis \equiv I must set aside some of my working hours for reading poetry.

$P_1 \equiv$ I will be earning a steady income a year earlier.

$C_1 \equiv$ I will not be a social success.

$P_2 \equiv$ I will be a useful member of society a year earlier.

$C_2 \equiv$ I will become one-sided.

Peter thinks that the degree of *validity* is the same for all four arguments. If anything is to tip the scales, it must be the difference in degree of *relevance*. The degree of relevance that Peter assigns to the various arguments is contingent on which higher norms (expressed or not) he accepts. As it happens, Peter believes that being a useful and prosperous citizen is preferable to being a person with a rich inner life but no money, and on this basis he accepts F_0 . We note that Peter assumes here that becoming more widely cultured will not lead to his becoming useful and prosperous, at least not as readily.

Example 3

Now we come to more complicated surveys. Let us take the example of students at an urban university in an occupied country during World War II who are discussing whether or not they should go on strike. A *pro et contra* list is made and used in the discussions. Most of the included arguments are of the kind one would already have heard from supporters and opponents of the scheme. (Note that the example given here does not altogether follow the rules just established. For instance, it infringes the rule for sepa-

SURVEYS OF ARGUMENTS FOR AND AGAINST A STANDPOINT

ration of levels of argument by adding, in pro argument P_7 , the phrase “this is a good thing.”)

$F_0 \equiv$ Students should strike (at the specified time).

Antithesis \equiv The students should not strike.

Pro Arguments

$P_1 \equiv$ Last week’s aggressive action against the university was so serious that a clear demonstration on the part of the students is called for. In this case, a strike would be the best course of action. (Precization of “clear demonstration”: a demonstration that will be recognized as such by non-participants.)

$P_2 \equiv$ A strike would strengthen the home front.

$P_3 \equiv$ The reputations of students, and indirectly of all intellectuals, will suffer a blow if they fail to show solidarity in time of war.

$P_4 \equiv$ A strike represents a small but nonetheless significant contribution to the common war effort, insofar as the morale of the military forces depends a great deal on that of the home front.

$P_5 \equiv$ A strike would effectively obstruct the attempts by the government to maintain and widen its own prestige in the country and elsewhere.

$P_6 \equiv$ A strike would effectively obstruct enemy propaganda by showing that cultural institutions cannot be preserved in an occupied country.

$P_7 \equiv$ Recognition of their own responsibilities strengthens morale among students, and this is a good thing.

$P_8 \equiv$ Last week’s strike attempt broke down. Unless they renew the attempt, students will have to recognize their own powerlessness, which will aggravate defeatism.

$P_9 \equiv$ A strike may provoke such threats that we will be justified in giving way, but the good consequences of the action (stated in P_1 through P_4) will not thereby be diminished, whereas all contra arguments, with one exception, will be weakened.

$P_{10} \equiv$ We still have the possibility of striking without serious consequences. However, we must expect such occasions to become increasingly rare. If the enemy adopts harsher methods, combined action will become impractical.

Contra Arguments

$C_1 \equiv$ It is to the enemy's advantage if we strike because they can then disperse the students, who, thus weakened, will be unable to voice their opinions effectively. In the city, students have better opportunities for keeping informed about the situation and for carrying out retaliatory activities.

$C_2 \equiv$ It is to our advantage to keep in close contact with those who waver in order to exercise influence on them.

$C_3 \equiv$ A strike affects different students to different degrees. Those who require technical apparatus will be especially hard hit.

$C_4 \equiv$ Students' economic positions will be adversely affected as a result of a strike. Some may be set back as many as two or three years, with a corresponding loss of income.

$C_5 \equiv$ Reprisals will follow upon strike action, which can be avoided by not striking. There may even be executions, perhaps of especially valuable people.

$C_6 \equiv$ If there is a strike, the enemy will take over all scientific institutions.

$C_7 \equiv$ The enemy will destroy important scientific apparatus and materials or use them in their war effort.

SURVEYS OF ARGUMENTS FOR AND AGAINST A STANDPOINT

- $C_8 \equiv$ At a given signal, students are able to mobilize armed groups, but only if they stay at the university.
- $C_9 \equiv$ If we attempt to undertake a strike and it is not effective, the operation will be a catastrophe. It is very likely that it will not be effective. (Precization of to be “effective”: the strike [1] must not interrupt education and must let the waverers go on to take their exams and acquire positions; [2] must not give outsiders the impression of dissension, thus making it easier for the enemy to occupy the vacancies; and [3] must not interrupt education and split the university into its separate faculties, which might then stand in opposition to one another.)
- $C_{10} \equiv$ Having no work will undermine morale, so that many students will abandon their vocations.
- $C_{11} \equiv$ When the students are out of work, the enemy will have all the more excuse to recruit them for compulsory labor to their own benefit.
- $C_{12} \equiv$ It will be to our country’s detriment to have a shortage of graduates when peace comes.

Contra-Contra Arguments

- $CC_1 \equiv$ a. If C_1 were true (arguments in support of F_0), then the National Assembly would already have closed the university last week.
b. This relates to P_6 and P_7 (possibly also to P_4 and P_5).
- $CC_2 \equiv$ a. The waverers will find just as strong opposition to the enemy in their home districts.
b. The distribution of news is just as good all over the country.
c. Some students at the university have gone over to the government.
d. For propaganda purposes, it is an advantage that active students be spread over a greater area.

e. Waverers are exposed to more effective enemy propaganda in the city than elsewhere.

$CC_3 \equiv$ A mitigating factor is that most students can, to some extent, continue their training outside the university by attending private courses and lectures. They can then take their exams as soon as possible after the return of peace. The delay will therefore be minimal.

$CC_4 \equiv$ Mitigating factors:

- a. For students from rural districts, it is cheaper to live at home than in the city.
- b. The food situation and conditions of life generally are much better in rural areas than in the city.
- c. If C_9 is correct, C_4 does not apply.

$CC_{6,7} \equiv$ If C_9 is correct, C_6 and C_7 do not apply.

$CC_8 \equiv$ It is easier to come militarily prepared from the rural districts if the occasion arises. Also, the occupation forces can more easily round up students in the city.

Example 4

A *pro et contra* survey for the following issue expression (see example 5 for an alternative survey):

$F_0 \equiv$ Our country should help underdeveloped countries.

SURVEY I

$T_0 = F_0$

$T_1 \equiv$ Our country should give technical and economic aid to some areas in Asia and Africa where the majority of people live at or below the subsistence level.

Pro Arguments

$P_1 \equiv$ Our citizens are morally obliged to accept F_0 .

SURVEYS OF ARGUMENTS FOR AND AGAINST A STANDPOINT

$P_1P_1 \equiv$ Our standard of living is so much higher than that of other peoples.

$P_2P_1 \equiv$ Our citizens honor the Christian code, in which love of one's neighbor is a basic principle.

$P_2 \equiv$ Accepting T_1 is necessary for saving our own way of life.

$P_1P_2 \equiv$ There is risk of war when so many are living below the subsistence level.

$P_2P_2 \equiv$ Our country should create new markets in these areas. We can only do so if these underdeveloped countries attain the economic prosperity required to establish commercial ties.

$P_3 \equiv$ Our country has special qualifications for contributing in this way.

$P_1P_3 \equiv$ The people in question cannot misinterpret our action as inspired by imperialism.

$P_2P_3 \equiv$ Our country is already well known for the humanitarian work of our missionaries in these countries.

Contra Arguments, Pro-Contra Arguments, and Contra-Pro-Contra Arguments

$C_1 \equiv$ No one is obliged to help these people.

$P_1C_1 \equiv$ They have largely themselves to blame for their plight.

$P_1P_1C_1 \equiv$ They are too lazy.

$P_2P_1C_1 \equiv$ They will not give up their religious beliefs, which play a large part in preventing progress.

$C_1P_1P_1C_1 \equiv$ Their laziness depends largely on weakness due to starvation, and in all probability it will disappear under improved economic conditions.

$C_2 \equiv$ Our country cannot help.

$P_1C_2 \equiv$ We have enough troubles of our own.

$P_2C_2 \equiv$ The help we can give will make little difference.

$C_1P_1C_2 \equiv$ Unlike the situation in these other countries, there is no risk of starvation in this country.

$C_1P_2C_2 \equiv$ Even the smallest contribution helps.

Example 5

Second *pro et contra* survey for

$F_0 =$ Our country should help underdeveloped countries.

SURVEY II

$T_0 = F_0$

$T_1 \equiv$ Our government, with the voluntary economic support of the people, should help those countries in which more than two-thirds of the population live in hunger, sickness, and need. (“Economically underdeveloped countries” is the internationally recognized designation for these countries. We will refer to them here simply as D .)

Antithesis \equiv We should not help D .

Pro Arguments (with one example of a contra-pro argument)

$P_1 \equiv D$ are a threat to world peace.

$P_1P_1 \equiv$ The people in D see how Western countries have exploited them.

$P_2P_1 \equiv$ The people in D will come to rise up against the oppression that they see to be the cause of their misery.

$P_2 \equiv$ Humanitarian considerations compel us to help the people in D .

$P_1P_2 \equiv$ Human solidarity must be extended over the whole world.

$P_1P_1P_2 \equiv$ It is in accord with our democratic principles and outlook on life.

SURVEYS OF ARGUMENTS FOR AND AGAINST A STANDPOINT

$P_2P_2 \equiv$ On ethical grounds, one cannot concede that the majority of mankind should live in extreme need while we live in comfort.

$P_1P_2P_2 \equiv$ The high standard of living enjoyed by developed countries is not due to themselves alone. The raw materials they have taken from D have contributed to this standard.

$P_3 \equiv$ According to the UN Charter we are pledged to give technical and economic assistance.

$C_1P_3 \equiv$ This country is not pledged to give additional *voluntary* assistance. We have already contributed what we are committed to under the terms of the UN Charter.

Contra Arguments, Pro-Contra Arguments, and Contra-Contra Arguments

$C_1 \equiv$ We do not have the economic capacity to give such assistance.

$P_1C_1 \equiv$ Our budget has already exceeded its limits.

$P_2C_1 \equiv$ Our country has a deficit in its overseas trade.

$C_2 \equiv$ We should first help the partially underdeveloped areas in our own country.

$C_1C_2 \equiv$ D present problems of a quite different kind and scope.

$C_3 \equiv$ We should first solve domestic problems of our own (such as housing and roads) before considering how we can help others.

$C_4 \equiv$ What little we can contribute is so inconsiderable that one cannot seriously speak of it in terms of assistance.

$C_1C_4 \equiv$ The significance of our assistance is not in economic support itself; our action will show the way to other Western countries when they seriously come to look for a solution to the problems presented by D .

$C_5 \equiv$ Such help will lead to overpopulation in D , which will just present further problems for the West.

- $P_1C_5 \equiv$ Better living conditions mean a decrease in the death rate of infants and an increase in population. Production of foodstuffs often does not keep pace with the rising population. If this is the case, then the West will have to stake even more capital to promote higher productivity in D .
- $C_1C_5 \equiv$ If D is provided with technical and economic opportunities to improve its living conditions, the people in D will themselves find some solution to the problem of the birth rate.
- $C_2C_5 \equiv$ An increased standard of living means an increase in the average age, so that D will have the benefit of more men in their prime. This means that the people in D can themselves increase production and foodstuffs.

VI

Effective Discussion

Introduction

We depend on language as a means of conveying ideas from one person to another. Often the views conveyed are not shared; opinion is divided. Then the exchange of ideas can take the form of debate. We can view some of Plato's dialogues as systematic attempts to clarify difficult issues and as such they represent good illustrations of the basic functions of debate.

From the time of Aristotle, people have noted the distinction between the rhetoric practiced by, for example, politicians and preachers and discursive or rational argument that is exclusively concerned with the critical exchange of ideas. These two forms of rhetoric cannot replace one another. Speech designed to arouse people to action or to have a direct influence on their behavior differs in kind from speech used purely in the exchange of ideas. To combine the two functions defeats the aims of each, namely, commitment on the one hand and clarity of thought on the other.

This chapter presents what we can regard as principles of effective discussion, although it might be more accurate to describe them as forms of irrelevance in serious discussion. The aim of effective discussion is the exchange of cognitive contents in a manner that facilitates the greater consistency and proper understanding of those contents. The principles are determined by this aim. Where our aims are different, these same principles or standards cannot be relevant and they may be directly harmful. If we wish to influence people and not to convince them, suggestiveness, propaganda, and advertisement are generally more effective means than discussion.

We shall consider irrelevance under six main headings. The definition we adopt for "relevant" in this context is such that "a matter x is relevant" means the same as " x infringes on none of the six principles for relevant discussion."

EFFECTIVE DISCUSSION

The principles themselves are elementary. They provide no more than a minimal basis for competent discursive argument. Finally, we must assume when using them that our discussion, whatever it is, concerns some fixed topic, namely that which is presented in the issue expression.

Principle One: Avoid Tendentious References to Side Issues

Preliminary formulation of principle one: *one should keep to the point, even if one is aware that it harms one's own interests to do so.*

Precization of the preliminary formulation of principle one:

A proposition *T* in a serious discussion violates principle one if (a) *T*, taken as an argument, has little relevance; (b) *T*, taken as an expression for an isolated assertion, is not sufficiently tenable to be able to support or detract from a given viewpoint; or (c) *T*, taken as a precization of or a comment on some previous argument is not conducive to highlighting misunderstandings. Principle one is also violated if *T* aims to influence people in favor of a certain conclusion.

Suppose that the topic for discussion is given in an issue expression in a *pro et contra* survey. The question whether some matter is irrelevant or uncertain will tend to be answered differently according to one's position regarding the issue expression. The first principle must therefore be interpreted as requiring only that a given matter be sufficiently relevant and tenable from one's own particular point of view. I illustrate this point with a conversation between two people discussing the issue of "for or against competitive sports," in which both are guilty of producing irrelevant arguments.

1. A: Competitive sports destroy a person's intelligence and spirit of cooperation.
2. B: A can only say that because he isn't a sportsman himself.
3. A: The last remark doesn't affect my argument, it only shows that I was right in saying sports destroy a person's intelligence.
4. B: You are a typical culture snob carping at sports whenever you can.
5. A: As I said before, I've no quarrel with sports as such, only with their harmful effects.

Principle Two: Avoid Tendentious Renderings of Other People's Views

Here assertion (2) is a clear case of irrelevant argument. Person *B* tries to throw suspicion on his opponent to weaken the latter's argument. Person *A*'s gibe at *B* in (3) is another case of irrelevance, as is *B*'s attempt in (4) to ascribe to *A* an argument that *A* disowns in (5). In this example, we see instances of two kinds of irrelevance: attempts to throw an opponent's view into disrepute by saying something that has nothing to do with the view itself, and attempts to attack an opponent for holding views that he does not hold.

Another form of irrelevant argument occurs when unnecessary emphasis is placed on some generally accepted viewpoint that even one's opponent would agree to. It can reinforce one's own position to subscribe to some sentiment that no one would criticize you for but which does not contribute materially to the discussion. By ignoring such banalities, an opponent, by his very silence on the point, may appear to be opposing them; he loses credibility and the other gains through cheating. In this way, spurious disagreement can be generated.

Principle Two: Avoid Tendentious Renderings of Other People's Views

Preliminary formulation of principle two: *an utterance in serious discussion that aims at rendering a point of view should be neutral in relation to all points of view represented in the discussion.*

Consider as a case in point a public debate on a country's economic policy. A politician *A* says, "We should agree to do away with all customs duties and try to get other countries to follow suit." A journalist *B* reports on *A*'s utterance under the headline, "Mr. *A* makes himself spokesman for a total free-trade policy." On reading the written version, reader *C* will already be influenced without knowing what *A*'s position really is. It could well be that *A* also expressed other views, and *B* cannot assume that *C* will be uninterested in these. If *B* expects *C* to adopt a negative standpoint to *A*'s views on free trade and thus expects that *C* can be shuffled into a generally negative attitude toward *A*'s other views, then *B*'s report is tendentious and hence irrelevant in its very selectiveness.

A common bad habit is to generalize an opponent's view, substituting "all *x* are *y*" for *A*'s "this *x* is *y*" or "some *x* are *y*." For example, "Men are better suited than women to be priests" becomes "All men are better suited than any woman to be priests."

EFFECTIVE DISCUSSION

Precization of the preliminary formulation of principle two:

An utterance in serious discussion that purports to give an account of A's viewpoint should be such that if we let the report stand in place of the original as an issue expression in a *pro et contra* survey, then none of the argument's force (tenability and relevance from A's standpoint) is lost.

Occasionally a report has to be made shorter than the original. In this case, it must inevitably diverge from the original and consequently it may yield a number of reasonable interpretations. The divergence, however, should not be biased. Distorting quotations is a familiar phenomenon, and one to beware of in this context. To take some saying or even a whole section of a speech out of its context may mean that far more misleading sets of interpretations become "reasonable."

The less a public knows about some debated viewpoints, the less competent it is to take a stand of its own, and thus the need for neutral presentation of the points of view in question increases. A teacher should be *less* brief with beginners than with more advanced students. Only when he can count on the listeners to know the contra arguments against his views can the teacher get down to *pro aut contra* arguing with the students. Beginners have smaller reserves of mature knowledge and are therefore more open to suggestion. To prevent uncritical reception of what he teaches, a teacher should take care to convey the rationality of a view along with the view itself.

Principle Three: Avoid Tendentious Ambiguity

Preliminary formulation of principle three: *the matter should not be communicated in a manner that incurs a real risk of misunderstanding on the part of the listener.*

Suppose a general in the armed forces proposes a truce to the enemy. The enemy answers that they agree to a 30-day truce. The same night they make an attack and win an easy victory. Afterward, they say they only agreed to a daytime truce, not a nighttime one as well. Their agreement to a 30-day truce was intentionally ambiguous.

Precization of the preliminary formulation of principle three:

An utterance in serious discussion violates principle three if and only if (1) the utterance can be given different interpretations and

it is possible for the listener to interpret it in a way different from that intended by the utterer, and (2) the listener's interpretation strengthens the utterer's argument more than the utterer's own interpretation would.

We can clarify the application of this principle with an example:

1. A: I have nothing against sports, but according to the view we Christians hold, I must say that . . .
2. B: "We Christians," who are they?
3. A: People like me who actively subscribe to Christian beliefs.
4. B: But think of all the people who call themselves Christian, do you speak for all of them?
5. A: Of course not, actually I meant members of the Christian People's party.

Let us now analyze this fragment of discussion in terms of relevance. Consider the following interpretations:

- $a_0 \equiv$ We Christians.
- $a_1 \equiv$ We who actively subscribe to Christian beliefs.
- $a_{1.1} \equiv$ We who actively subscribe to Christian beliefs in the political sphere as well.
- $a_{1.2} \equiv$ We who actively subscribe to Christian beliefs politically or otherwise.
- $a_2 \equiv$ We members of the Christian People's political party.
- $a_3 \equiv$ We who adopted the Christian faith and morality.

Speaker A uses a_0 , $a_{1.1}$, and a_2 as cognitively equivalent — although the word "actually" in (5) can mean something else (see next paragraph). Probably $a_{1.2}$ and a_3 are reasonable interpretations, and A can be presumed to be aware of this. But A employs a special usage. If in this context, by a_0 he means a_2 , his listener will tend to confuse the reasonable interpretations that thus lead to a quantitative and evaluative overrating of the group that A represents. Members of the Christian People's political party make up only a small portion of those normally rated as Christians, in the sense un-

derstood by $a_{1.2}$ or a_3 . If A did represent the whole class, his standpoint would not be politically colored and would therefore acquire a greater authority. However, he would then succeed in arousing the opposition of Christians in senses other than $a_{1.2}$ and a_3 . By adopting sense a_0 , A might find it easier to influence his listeners into accepting his own standpoint. Thus, A 's use of a_0 is a sign of irrelevance.

This use of tendentious ambiguity can certainly be weakened by the listener's knowledge that the speaker is a member of the party in question and that its members normally interpret a_0 as a_2 . Assertion (4) to some extent supports the supposition that such knowledge holds in this case. Listener B 's remark implies that he interprets a_0 as $a_{1.1}$ rather than as $a_{1.2}$.

In regard to the relevance of A 's argument, it is also in A 's favor that in (5) he recognizes his special usage instead of attempting to cover it up with some irrelevant remark. If A had deliberately produced an irrelevant argument, there would be, psychologically, less likelihood of his uttering (5), since this utterance clearly confirms one's suspicion about irrelevance.

A tendency toward irrelevant argument can perhaps be detected at assertion (3). Quite likely A understands what B hints at when he utters assertion (2), but does not manage immediately to resist the temptation to offer the ambiguous expression a_1 instead of the more precise a_2 .

Assertion (2) is in the form of a question, but presumably B is aware that by a_0 A probably means a_2 and that A does not imagine all people subsumable under $a_{1.2}$ or a_3 are in favor of his own standpoint. Perhaps, too, B thinks the rest of his listeners are aware of this. Under these assumptions, B interrupts A with (2), insofar as (4) is a symptom of B 's irrelevant arguing. He draws the attention of possible opponents to A within group $a_{1.2}$, and at the same time deals A a blow. But according to the above assumptions, the interruption, because it is definitely misleading, cannot be justified as a technique in discussion.

We conclude that we have a sign of A 's, and possibly also of B 's, infringement of principle three.

Principle Four: Avoid Tendentious Argument from Alleged Implication

Principle two refers to nonneutral renderings of other people's views. Principle four refers to tendentious presentations of other people's views, which

Principle Four: Avoid Tendentious Argument from Alleged Implication

associate inductive or deductive consequences with *T* that do not directly follow from reports of previously formulated standpoints.

It is, of course, entirely acceptable to judge proposition *T*, not only on the basis of the assertions made by the proponents of *T* but also on the basis of propositions that one believes are deductive or inductive consequences of *T*, or which in some way give a fuller presentation of the viewpoint expressed by *T*. However, when giving an account of the view *T* states, it is tendentious to attribute to proponents of this view assertions that one assumes or considers to be inferred from *T*.

For example, someone argues as follows: "Opponents say that he accepts *T*. But from *T* follows *U*, and *U* is untenable. Therefore *T* is untenable." Here it is important to know whether an opponent does in fact accept that *U* follows from *T*. If he does not and yet we proceed under the assumption that he does, then we have broken an elementary rule for relevant discussion. In addition, it can be tendentious for us to introduce *U* at all before we have discussed whether *U* does or does not follow from *T*.

Another kind of tendentious imputation occurs when one says that certainly *A* says he accepts *T* but that he does not mean it; his real view is *U*. For example, "*A* says he honors the principle about equal rights for higher education whatever the financial circumstances, but in fact he thinks that this right ought to be confined to those who have the means to undertake a prolonged course of study."

In another case, someone asserts that *A* certainly means *T*, but also means *U*, which is inconsistent with *T*. For example, "*A* supports the greatest possible freedom. But freedom for whom? From all accounts, it seems he only wants freedom for people who share his viewpoint, which is that freedom can only be realized after a period of oppression."

There is, of course, nothing to prevent a person from saying one thing but meaning another. Indeed, the accounts people give of their views are often deliberately vague and misleading. Thus, imputations of the kind discussed here often prove to be justified. However, unless the imputation is clearly presented as a hypothesis, together with the grounds for accepting it, the account itself will be tendentious and misleading. Generally, fruitful exchanges of thought are impeded by hasty assertions that attribute a viewpoint to one's opponents that is either immaterial or inconsistent with what they say they mean. In the end, one creates a sort of personal isolation in the face of one's opponents that easily generates ill will and even violence.

EFFECTIVE DISCUSSION

Preliminary formulation of principle four: *one should give an account of another person's viewpoint (1) without saying whether the person in question is likely to accept the account or (2) without bringing up the arguments one has for attributing to someone a view he himself says he does not hold.*

Precization of the preliminary formulation of principle four:

An utterance in serious discussion violates principle four if, and only if, it attributes to a person (or group) a viewpoint (assertion, opinion, or argument) and the following three conditions are fulfilled: (1) *A* does not agree to *T*, and the speaker fails to produce arguments to show that *A* supports *T* or fails to mention the viewpoints that *A* has expressed; (2) the difference between the viewpoint that the public will probably attribute to *A*, if it believes the speaker, and the standpoint that the public would reasonably take *A* to hold if *A* had a chance to speak for himself, affects the issue's acceptability positively or negatively, or affects the combined strength of evidence in pro or in contra arguments; and (3) this difference strengthens the speaker's (or his group's) standpoint. The application of this principle can be clarified with an example:

A: The country's economy should continue to be run on the principles of a planned economy.

B: It seems from *A*'s standpoint that he does not mind recommending a policy that will lead to our country's ceasing to be a democracy and to our people's being deprived of their freedom as they were during the war. But freedom is such a valuable thing that there can be no question of exchanging it for some possible economic advantage.

Person *B*'s first sentence is designed to arouse in his listeners the idea that *A* accepts the consequences *B* extorts from *A*'s utterances. But there is no indication that *A* would in fact accept them. We must assume that *B* is aware of this and of the probable reaction of his listeners. Person *B* should first have given reasons for his view that *A*'s proposal will incur the consequences he, but hardly *A*, assumes it will. Only then should *B* go on to criticize *A*. If "freedom" and "democracy" are used with as much emotive value as *A*'s and *B*'s listeners normally derive from them, any views that are detrimental to freedom and democracy will arouse the public's antipathy. Speaker

B's words practically *compel* support for his own position in the debate, as he no doubt intends. We conclude that *B* is guilty of violating principle four.

Principle Five: Avoid Tendentious Firsthand Reports

Preliminary formulation of principle five: *an account (descriptive or theoretical) violates principle five if it leaves something out and lays emphasis on other things, or in some other way conveys a distorted impression to the listener, or else gives a directly false impression that serves the interests of the speaker.*

The application of principle five is illustrated by the following example:

A: We must go and catch the train now; it's just 9 o'clock.

B: No, I'll change my clothes first; it's only a quarter to.

In fact, *A*'s watch shows 8:55 and *B*'s 8:50.

Person *A* gives a false impression of what he has observed. So does *B*. Speaker *A*'s tendentious report of what he sees supports his wish to be getting on his way, while *B*'s account is designed to cater to his inclination to linger awhile.

An analysis of this kind becomes less sure the closer *A*'s and *B*'s accounts come to that of some independent witness and the less anything depends on the observations. A witness's account itself then becomes suspect if there is reason to believe that it is designed to prove irrelevant on the part of *A* or *B* or both.

Precization of principle five:

A proposition *T* in serious discussion violates principle five if, and only if, (1) *T* provides an account of observations (or of the relationship between observations) that is incorrect or incomplete or *T* holds back information that must be considered relevant in judging the validity or relevance of an argument, and (2) deviations that occur are intended to strengthen the speaker's position in the debate.

We can clarify the application of principle five with another example. Suppose a correspondent of a foreign newspaper reports the result of a parliamentary election in a telegram as "The *A* party increased its vote." A

EFFECTIVE DISCUSSION

more neutral and comprehensive account might show, however, that although the *A* party did indeed “increase” its vote, its proportion of the total votes cast decreased. The telegram presents party *A* in a favorable light at the cost of the others. We conclude that the correspondent has violated principle five.

Principle Six: Avoid Tendentious Use of Contexts

This principle concerns the context (or conditions) in which a matter is brought forward. In this category, we include in the context both noncognitive and cognitive components in, or as accessories to, the argument. This includes expressions of the following kind: “When a hypocrite such as Mr. H. starts saying what he feels, one knows straight off that. . . .” Any use of terminology of a scornful, abusive, or otherwise nonargumentative nature can come into what we call the “context” of the discussion. In addition, there are properties of the broader context in which the discussion is presented, such as the use of music, pageantry, serving of food and drink, and any other accessories of persuasion and suggestion. In the case of newspaper articles, for instance, it can be a question of the selection of type, photographs, and so on.

Preliminary formulation of principle six: *a matter should be presented in a neutral way in a neutral setting.*

Precization of the preliminary formulation of principle six:

An utterance in a serious discussion violates principle six if, and only if, the context in a wide as well as a narrow sense serves to strengthen the position of the speaker without its influence being attributable to the cognitive context of the matter.

Review of Principles

I will now briefly recapitulate the six principles for effective discussion.

Principle one concerns utterances (1) that are falsely presented as *arguments* for or against a position, or as precizations of arguments, or (2) that have a tendency to be so interpreted by the public.

Principle two concerns utterances (1) that are falsely presented as direct accounts or reports of previously presented viewpoints or (2) that have a

tendency to be so interpreted by the public. Principle two concerns a class of expressions that sometimes form part of an argument but that more properly belong to separate discussions of the status of the opponent's material and viewpoint in the discussion.

Principle three concerns the same utterances that principle one applies to, but refers specifically to the introduction of ambiguity to promote misunderstanding.

Principle four concerns expressions that assert something about the standpoints of others but that cannot lay claim to being direct accounts and that are not intended to be understood as direct accounts. Such expressions often occur in the form of conclusions drawn from one's opponent's own utterances ("If *A* means *T*, then he must also accept *U*").

Principle five concerns utterances that claim to belong to the *common pool of evidence* upon which any judgment of an argument's validity or relevance is to be based. Included among these utterances are reports of observations, the contents of textbooks, and works of reference that aim to represent our common knowledge.

Principle six concerns the relationship of utterances to the *wider context*, including the linguistic context in which they occur.

Common to all utterances that are open to violate these six principles is the precondition that they either actually occur in serious discussion or else are intended to be used in such with a view toward substantiating an argument's validity and relevance. A "serious discussion" is defined as any discussion in which the main aim is to increase one's understanding of some definite problem or in which one tries to clarify the issues involved in coming to a certain important decision. A further requirement of all utterances and other relevant factors liable to violate these principles is that they serve to strengthen, in the listener's mind, the standpoint that the speaker or spokesperson adopts in the discussion.

One of the main reasons for setting out in detail the rules for avoiding irrelevant arguing is that, by making the pitfalls explicit, one sees clearly how hard it is to justify any claim about irrelevant arguing. This chapter is not meant merely to improve the student's defenses, to put him on guard against irrelevant arguments directed at him; its primary purpose is to show the reader what he opens himself to when he makes accusations of irrelevant argumentation against others. One must be able to provide a satisfactory motivation for someone's violating a principle of relevance. When

EFFECTIVE DISCUSSION

an accusation of this kind comes up in a discussion that is itself not concerned with the relevance of arguments, it can often lead to a case of violation of principle one about tendentious references to side issues. *Accusations concerning the introduction of irrelevant arguments are one of the most common forms of irrelevant argument.*

If we suspect an opponent of making tendentious remarks, a grasp of the principles can help us judge whether our suspicions are well founded. But whatever our conclusions, the discussion itself will determine how well we can assure ourselves that the topic our opponent takes up is irrelevant to the subject of the discussion. If you think that you perceive a tendency in your opponent to try to win people over, say, by designedly ambiguous terms, you must be able to identify the ambiguities, at least to yourself. The first step toward testing such a belief is actually to formulate more precise expressions than those used by the opponent.

Distinction Between Relevant Argument and Forms of Persuasion

There is a great difference between a relevant or competent debate, on the one hand, and advertisements for goods or attitude conditioning through propaganda, on the other. It is important to realize that the various ways of influencing people's predispositions are not necessarily to be judged as though their aim was to promote competent discussion. Thus, the question of irrelevance only arises if such influencing appears in the guise of material for debate.

The slogan "truth in advertising" has served as an organizing principle for many attempts to combat the tendentiousness and inaccuracy of modern advertisers. But techniques in the art of public relations and advertising are various and subtle. So, too, with propaganda; despite all efforts, people are still unable to effectively combat the power and appeal of the skillful propagandizer, especially where sociological factors are at work.

One of the least debatable principles of the scientific approach is to realize as consistently as possible the distinction between relevant argument and forms of persuasion. The distinction has not always been appreciated. One comes across scientific works from the sixteenth and seventeenth centuries containing a great deal of inconsequent material of a persuasive kind, sometimes including religious doctrines cited as undeniable premises in ar-

gument. In our own century, when scientists are especially concerned with sociological matters, it is particularly important to distinguish between pronouncements and propositions.

The connection between the principles of relevant discussion and the previous chapters of this book may seem a little unclear. The connection is this: the misuse of language, especially insufficient use of precization, paves the way for all the usual aspects of irrelevance discussed here. It is precisely in precization that one finds the instrument to combat incompetent discussion. The technique of precization, then, is of great importance.

According to the way the term “relevant” has been introduced in this chapter, the principles governing relevance are essentially independent of whether the issue expressions or arguments belong to some well-established science. “Relevant” does not mean the same as “technical” or “scientifically based.” Indeed, one especially significant area of discussion in which these principles apply is when people argue, not about things, but about competing evaluations and when the issue expression is normative. We should note here that the acceptance of the democratic system, which most of us critically or uncritically subscribe to, itself presupposes a competent discussion on questions of value.

Political spokespeople and writers are often accused of employing irrelevant arguments when what they say seems to be entirely wrong or long since refuted. But it is clear from the principles presented here that *disagreement*, however deep, is not a sufficient reason for accusing the person one disagrees with of employing irrelevant arguments. A newspaper can be completely biased and yet validly claim that its opinions are not the outcome of irrelevant or immaterial argumentation. One may attack it for its one-sidedness but not for its irrelevance, however much one feels its views can only have been arrived at through tendentious selection and distortion of the facts.

For the same reasons, when people preach, we cannot accuse them of the sins enumerated in this chapter. On the contrary, as soon as we ourselves purport to represent an opponent’s view — whether in a scientific, religious, ethical, or political context — our account can be incompetent in any of the ways described.

Series Editor's Introduction

Arne Naess — A Wandering Wonderer: Bringing the Search for Wisdom Back to Life

[The pre-Socratics'] attitude, in the main, was genuinely scientific whenever it did not merely embody the prejudices of their age. But it was not *only* scientific; it was imaginative and vigorous and filled with the delight of adventure. They were interested in everything—meteors and eclipses, fishes and whirlwinds, religion and morality; with a penetrating intellect they combined the zest of children.

From this point onwards, there are first certain seeds of decay, in spite of previously unmatched achievement, and then a gradual decadence. What is amiss, even in the best philosophy after Democritus, is an undue emphasis on man as compared with the universe.

Bertrand Russell, *History of Western Philosophy*

When the full scope of Arne Naess's philosophical contribution is examined carefully and placed in context, it will very likely be viewed as one of the twentieth century's most significant and enduring.¹ Naess has made bold and innovative contributions to conventional academic philosophy and social research, particularly in the areas of behaviorist epistemology, empirical semantics and communication theory, scepticism, scientific and cultural pluralism, Gandhi and Spinoza scholarship, normative systems theory (as a general approach for exploring premise-conclusion relations), and the very idea and relevance of total systems (total views in Naess's *lingua*). Perhaps even more significant—although one should not view it as distinct or decoupled—has been his commitment to reconnect philosophy to life experience. This effort is similar to Bertrand Russell's in that it has been particularly pronounced in later life. Naess, however, carries this com-

SERIES EDITOR'S INTRODUCTION

mitment to expand philosophy's sphere of concern to life in general and the Earth. Essential to this endeavor, is the mature Naess's radical initiative to reconceptualize reason expansively, to integrate reason with emotions and feelings *in practice*. In some cases this includes using mythopoetics to make a case or communicate a point.² What makes Naess so special is that even while paddling against the current, he exhibits tremendous optimism and openness, joy, and a disarming, infectious playfulness.

Naess strives to *live his philosophy*. For more than thirty years, he has sought to reshape the philosophical debate by drawing from and building on his previous work to outline a nondualistic, nonanthropocentric philosophy of life that affirms the ultimate unity and interdependence of all living beings, while maintaining their individuality. His philosophy celebrates the Earth's richness and diversity—both cultural and biological. That said, one of the main purposes of the *Selected Works of Arne Naess* (SWAN), however, is to provide you, the reader, with the resources to make your own informed judgment regarding the significance of Naess's philosophical legacy.

At age ninety-two, Arne Naess has lived a long life filled with wonder. In his words, he has “seen life”—traveling the world, spending significant periods of time on every continent. He has experienced the world somatically and intellectually in concert as one mind-body—as a being—and seen more than most of us can imagine.

When Naess was born, Archduke Francis Ferdinand was alive, automobiles were in their infancy, and most homes did not have running water. Home refrigerators had just begun to be produced. Television and computers were only imagined. Only a few years before, after being contemplated for millennia, the first controlled and sustained powered flight took place, ushering in a period of ever-accelerating transfer of materials and information, but not necessarily a commensurate increase in knowledge or wisdom.

Consider that Naess has lived through two world wars (and too many “limited” conflicts to count), the rise and fall of the Soviet Union and East Germany, the “liberation” of India and Pakistan, the onset of climate change, and the hastening of “global terrorism.” He has been the beneficiary of tremendous medical advances and unprecedented economic growth, and he has seen the ravages caused by escalating consumption, globalization, and disparities in both income distribution and access to resources. He is part and product of humanity's largest growth spurt. And he

has witnessed the most significant loss of cultural diversity and the onset of what may become the planet's greatest extinction crisis—but is surely the greatest extinction crisis ever caused by one of Earth's own species. Naess has also seen and, at times, participated in the many hopeful responses to these ills—the peace, social justice, and ecology movements; nonviolent actions to support antiglobalization efforts and protest dam building; voluntary simplicity; conservation biology; wildlands philanthropy; bioregionalism; green business and architecture; ecological design, economics, engineering, and restoration; and sustainable agriculture, forestry, and fisheries management.

Everyone is influenced by the times and events of his or her day. The “prejudices of our age” filter into our lives and work more or less consciously and actively, but at a minimum they enter passively. What is the mature Naess's approach to philosophy, how is it a uniquely self-aware and responsive product of his day, and why should it be seen as monumental?

Naess likes to see himself as a “philosopher of life.” The thought of simply being an academic philosopher—living a life of the mind—makes him restless and uneasy. For Naess, “wonder” is both the point of departure for philosophy and the focus of the enterprise. He is the philosophical equivalent of a hunter-gatherer using his wits and intuition to seek out food (for thought) in a fecund landscape. As they were for the ancient Greeks, science and philosophy are inextricably intertwined for Naess. Science, as the application of reason through empirical investigation, cannot be separated from rational reflection on the nature of reason, and vice versa. For the mature Naess, though, philosophy and science are also distinct. Philosophy is the unique realm in which we take up the deepest, most profound, and most fundamental problems. From Naess's vantage, which defines philosophy openly and discursively, the questions that have fascinated and plagued people for millennia have not changed much and they are not likely to change significantly in the future.

Naess's view of philosophy includes the traditional epistemological question “What can we know?” and the ontological question “What main kinds of things are there?” But it also includes “How do we measure?” and “How do we know?” as well as “What is the relationship between the knower and the known?”³ These are questions that are likely to vary with cultural and social circumstances, but this does not, for Naess, imply cul-

SERIES EDITOR'S INTRODUCTION

tural relativism. By its nature, this view of philosophy runs counter to the dream of the logical empiricists; it cannot be restricted to investigations of “fact” or “logic.” It is imbued with fundamental valuations. Being a philosopher, for Naess, is thus a deeply personal and intimate matter that requires us to engage all of our powers and experience. It should also include questions such as “What are your aims in life?” and “What’s driving you?” as well as encourage a practice of deep and open argumentation by asking repeatedly, “Why do you hold that *p*?” in order to unearth underlying premises and hypotheses. For Naess, all these questions have an empirical component. He sees it as a duty for a philosopher to extend research into the creation and use of empirical methods to address these aspects, unless these questions can be adequately addressed by an existing empirical science, in which case it is fine for a philosopher to perform research here, but it no longer constitutes a *duty*.

In Naess’s view, philosophy is ultimately concerned with how *we*, through our experiences, perceive the world, the world’s relation to ourselves, and the basic features of the condition of people. It is the realm in which we pose sophisticated questions to address perennial problems, probe them from different angles (in Naess’s case, from as many angles as possible), and test and apply the insights to real life—to what we do and decide every day. Its purpose is not to arrive at definitive answers. The purpose of philosophy, rather, is to help us understand what *we* believe in from our innermost perspective, expand this perspective continually, and facilitate communication—so that we might contribute toward improving the state of affairs of the world.

While initially attracted to Bergson’s *les données immédiates de la conscience* (the immediate data of consciousness), Naess grew disenchanted when he recognized that one becomes lodged in an endless circular loop and never exits consciousness. Naess clearly believes that the unexamined life is not worth living (his life is a testament to Socrates’ edict), but he appreciates that disembodied, introspective examination comes at great peril. A mind-centered focus on “examination”—where subjects exist separately from objects, theory is isolated from praxis, and knowledge is decoupled from wisdom—very quickly degenerates into meaninglessness. Worse yet, separating people from and raising people above nature and the coevolutionary process that created us—and provides for our sustenance—can be inimical to life and the evolutionary process.

Nature, that which is, the reality of the pre-Socratics, is Naess's philosophical palette, not the "world" of his own consciousness as has become the norm with so many contemporary philosophers since Descartes. Popper and others posit the existence of three worlds that correspond to the development of our commonsense view of reality. World I is the physical world, the "external world," the world of our sensory impressions. World II is the world of all conscious experience, the psychological world of the "immediately given," which incorporates our feelings and intentions. World III emphasizes the logical content of reality. Naess finds these multiple views of reality unconvincing and potentially dangerous. With a worldview inspired by Spinoza's *Ethics*, he is fundamentally opposed to the notion of multiple worlds.

Naess's mature philosophical approach and contributions are shaped by full engagement with a relational reality, in which no firm subject/object, substance/property, universal/particular, fact/value dualities exist. John Muir's famous, deceptively simple aphorism sets the stage: "When we try to pick out anything by itself, we find it hitched to everything else in the universe." Reality as we experience it, according to Naess, is a dynamic, multilayered manifold of hierarchically related gestalts—of which we are always a part. It is the opposite of atomism. Contrary to the dominant, Western way of viewing reality, there are no extrinsically connected discrete objects or "things in themselves" in the sense of Kant's *Ding an sich*. With Naess's "gestalt ontology," there is no dualistic "I" standing outside of reality looking in. Living beings, individuals in the sense of Spinoza's modes, are spatiotemporal manifestations of "one substance," nature or reality. As Naess points out in *Freedom, Emotion, and Self-Subsistence* (SWAN VI), Spinoza's medieval terminology of substance, mode, attribute, God, and Nature is dispensable. In addition, Naess goes on to characterize "living beings" broadly to include individual organisms as well as ecosystems, rivers, mountains, and possibly Earth (Gaia).

Naess's view of reality calls for a gestalt shift. His gestalt ontology does not stop with gestalt psychology's simple notion of holism, where the whole is more than the sum of the parts. It goes on to add that the internally related subordinate gestalts are themselves more than mere parts. There are no parts as parts or wholes as wholes; higher-order wholes are not reducible to lower-order wholes. The concrete contents of reality have gestalt character. For Naess, we experience reality spontaneously and our

SERIES EDITOR'S INTRODUCTION

experience of the world is made up of gestalts. “[This] is the world we experience. Nothing is more real.”⁴ People create abstract structures to reflect on or analyze spontaneous experiences and their structure; they are the interrelations between spontaneous experiences. Mind and body are mental contrivances and conveniences—abstract structures in Naess’s parlance—for helping us to describe, model, or understand certain states of affairs. They are not the contents of reality. Only individual occurrences of spontaneous experience make up the concrete contents of reality.

What are the consequences of Naess’s “ontological realism” as expressed in the form of gestalt ontology? First, living organisms have different levels of access to reality, based on their capacities, experiences, and backgrounds. This implication of “reality is one” plays a central role in the mature Naess’s approach to philosophy of science. One of his main thrusts is to undermine the claim that the exact physical sciences show all that is, that they have a privileged view of reality. In his view, science creates extremely abstract structures of what is real, but those structures do not actually *describe* any of reality’s concrete contents (descriptions are themselves normative). Jakob von Uexküll, the famous ethologist of the early twentieth century, whom Naess read closely in his youth, helps clarify this notion. “As the spider spins its threads, every subject spins his relations to certain characteristics of the things around him, and weaves them into a firm web which carries his existence.”⁵

Different people experience reality differently, yet we often, incorrectly, speak of *different realities* as if they existed. By the same token, identical accounts of reality in no way imply verification of that view by correspondence; from Naess’s perspective, such accounts by themselves are merely a sign of cultural poverty. “God” could have created the Earth and life 6,000 years ago, but the evidence to support this case is thin and the evidence to support evolution is stronger, in part because biological science and paleontology generally employ a greater level of depth of intention and thus aspire to maintain higher standards for the evaluation of evidence. Radical pluralism and scientific possibilism do not imply scientific or ethical relativism.

There are at least four other key implications of Naess’s gestalt ontology. First, the existence of one, interdependent reality tends to curb solipsism. Second, the world we live in spontaneously can no longer be characterized as merely subjective. Expressions such as “the social construction of

nature" become oxymoronic. Third, individual organisms exist as knots in a biospherical web or net. Reality is not anthropocentric; it is not particular to humans. Fourth, humanity can no longer justifiably be seen in opposition to a separate object—nature. This insight tends to temper any "natural" tendencies toward anthropocentrism. As with Leopold's Land Ethic, people become plain members and citizens of the biotic community, albeit ones with unique powers and proclivities and thus special responsibilities. We are all individual beings, yet we vary in the extent to which we are integrated into the whole.

Humans are massively altering the gestalt character of reality, diminishing it, making it less complex. We do this, Naess argues, without necessarily recognizing we are doing it or the extent to which we are doing it. Thus, we are unable to evaluate the tradeoffs of making such decisions. Naess argues that we generally act simply according to how we "see" reality, but there are aspects of reality that may not be available to us. These aspects are no less there because they are currently unavailable to us, yet they can be destroyed very easily. Sometimes we also confuse our abstract structures of reality (models, data, concepts, etc.) with the contents of reality and vastly underestimate the complexity of internal relations between gestalts, leading ourselves to believe, incorrectly, that higher-order wholes can be reduced to lower-order wholes. It is Naess's hope that by embracing gestalt ontology, we are encouraged to cultivate our opportunities and faculties for experiencing reality more fully—for experiencing more complex, higher-order gestalts. It is also his hope that we will openly and more carefully consider, in advance, how a proposed research program, action, or decision might affect other peoples' (or other life-forms') opportunities for rich spontaneous experiences (consider, for example, the possible impacts of ostensibly beneficial research on nuclear fission or molecular biology). In the end, however, we should remember Naess's own caution—his description of gestalt ontology is itself an abstract structure. As Naess says, "For me reality has always been something slippery to handle. I seem to grasp it firmly, but like an eel, or even a small lively trout in shallow water, firmness of grasp does not guarantee against escape."⁶ But does reality really have gestalt character?

Truth—as in *the* truth—is not a defensible notion for Naess. For too many academic philosophers, wonder has been extinguished and replaced

SERIES EDITOR'S INTRODUCTION

by a belief that definitive answers have been found, that the original, initially vexing questions can be laid to rest. Naess is under no such illusion. He views humans as essentially fallible and he sees this domain of fallibility as extending to mathematics and formal logic. This may be why he so freely returns to previously explored material (sometimes just after writing it) and looks at it afresh, with new and frequently competing and even conflicting insights. For Naess, truth is something we seek continually without expecting or believing that it can be found. He seeks peace of mind (*ataraxia*) by suspending judgment (*epoché*). While necessity requires him to take firm positions in life, he often resists taking such positions in his written philosophy. Having reached a general state of mental suspense (*isothenia*), he prefers, as a mature sceptic, anticipating his own tendency to come up with counterarguments and counter-counterarguments, to suggest alternative paths, inspire new ways of looking at things, and foster informed, open-minded debate. This *zetetic* inclination, although nascent in many of his earlier works, was made explicit and became a central theme in his philosophical writings in the 1960s.

For Naess, passivity has no place in philosophy or life. In his famous debate with Sir Alfred Ayer, Naess defines Spinoza's *amor intellectualis* as a "kind of loving attitude towards what you have insight into, while considering it in an extremely wide perspective."⁷ For the mature Naess, *amor intellectualis* involves using his technical and intellectual training to articulate, in direct and forceful ways, his attitudes and evaluations on matters of practical consequence. Like Spinoza and Gandhi, Naess is concerned with human salvation in this world, but Naess, with his concept of "wide-identification," expands this concern to both humankind's relationship to life in general and the self-realization of all life-forms for their own sake. Whether it be understanding how lay people conceptualize truth or experts characterize democracy; considering how our approach to science not only shapes how we do science, but the nature of scientific outcomes too; using philosophy to improve practical communication; facilitating thoughtful debate on the potential dangers of Norway joining the European Union; or discussing the ethics of climbing, the meanings of sustainable development, or distinctions between different approaches for addressing the ecological crisis, Naess seamlessly connects philosophical questioning to activeness in relation to the questions.

Naess's philosophical career can be seen, in one sense, as an attempt to

bridge C. P. Snow's two cultures. Believing that the central questions of philosophy are here to stay, he has developed his philosophy over seventy years in part through his effort to relate these questions to the issues of his rapidly changing, trying, and tumultuous era. Naess's lifelong commitment to integrate interests in nature, science, and logic is evidenced by the mature Naess's championing of philosophical approaches in which both metaphysics and science contribute to all-embracing systems of thought. This approach is particularly prominent in Naess's development of normative systems theory, a strategy for promoting systematic reflection on premises and conclusions. Recognizing that all philosophical questioning must stop somewhere, Naess calls the essential intuitions that serve as bedrock assumptions for our total views, ultimate norms or ultimate premises. Further, recognizing that our philosophical conclusions as well as our lifestyles and everyday actions often appear inconsistent with these ultimate premises, Naess has developed a strategy for using premise-conclusion strings to help identify potential norm conflicts as well as to help assess whether potential agreements and disagreements are real or pseudo. Use of this technique figures prominently in Naess's approach for improving communication, in his approach for exploring both the philosophical basis for Gandhi's *satyāgraha* (active nonviolent resistance) and the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," as well as in his own Ecosophy T.⁸

With regard to total views—broad philosophical systems like Spinoza's, which attempt to communicate our deepest insights and communicate views of life—Naess argues that although the existence of complete, explicit total views is absurd, it is equally absurd to presume to criticize a total view without adopting one (at least implicitly). After relinquishing the possibility of creating a consistent empirical theory of knowledge, Naess came to believe that any theory of knowledge presupposes all major philosophical disciplines, at least on the metalevel. One cannot have a theory of knowledge without presuming a particular reality, at least implicitly, and this necessitates having an ontology, metaphysics, ethics, and so on. This has practical consequences too. We never simply act solely as a philosophy professor who specializes in logic or ethics; we are always, at least partly, mother, daughter, lover, scientist, . . . , and philosopher. If we accept the premise "For every decision we, explicitly or implicitly, take all things into consideration," then the notion of total views or total normative sys-

SERIES EDITOR'S INTRODUCTION

tems can be seen as very “useful fictions,” which, if articulated, might help us to improve decision making.

Naess is careful to point out that he sees his own total view and others as fragmentary and constantly evolving—ever “on the way.” Moreover, even if we could have a completely formed and integrated total view, we could not count on being able to articulate it. There will always be a tension between the Spinozistic goal of clarity and the pragmatic reality that in this world we can never wait until all the facts are in. None of these issues, however, justifies abdicating our responsibility to try to articulate our own total views. The mature Naess is a radical pluralist. He believes in defending coherent systems, without claiming that their relation to reality is definitive. While he is committed to the importance of models and systems, he is opposed to the idea that there could or should be a definite worldview. Naess's hope is that there will be no definite scientific worldview in the future.

No Western philosopher since Descartes—except perhaps Spinoza, who has also been a primary inspiration for Naess—has had the potential to help us drastically reshape our relationship to each other and life in general: not by spelling out *a* clear and coherent total system—to be taken as *the* truth—but by challenging us to articulate our fragmentary total views and connect the abstract problems of philosophy to issues of contemporary social and political conflict. In Naess's view, “[t]he full meaning of a theory can only reveal itself in practice, and practice is blind without theory.”⁹ To be a philosopher of life, one must embrace both theory and practice and engage them in dance.

In Norway, Arne Naess is regarded as a national treasure, a seeker and a seer, a “minor prophet,” in his own words. His radical pluralism and endorsement of diversity are demonstrated by his complex character. He has a proclivity for being aloof and charming, somber and joyful, accountable and carefree, arrogant and modest, slippery and precise. In a world of contradictions—breathtaking beauty *and* ineffable squalor and suffering—Naess is no exception. He is an antiguru guru. He strives for high levels of consistency and integration in his philosophy but accepts that in his personal life he cannot live up to his philosophical systems' requirements. He strives for definiteness of intention, yet he appreciates vagueness and eschews dogma, refusing

to be pinned down to a particular viewpoint or placed in a particular philosophical camp. This stance is further supported by his sometimes maddening tendency to revise, revise, and re-revise. As a consequence, one cannot go to any of his books or articles and find the "definitive" Arne Naess. He is a troublemaker too, but the kind of troublemaker people want to have around because he challenges orthodoxies with an elfin irreverence. Naess stands out because his frequently outlandish and controversial views are felt deeply, reasoned carefully, and conveyed playfully.

Naess has had a profound influence on Norwegian academic life and the society as a whole. From 1939 to 1954 he was Norway's only professor of philosophy. He was chiefly responsible for organizing courses for the *examen philosophicum*, introductory examinations in logic, methodology, and history of philosophy that an entire generation of undergraduates (roughly 100,000 people) were required to take, regardless of their disciplinary focus. His unique paradigm of inquiry—emphasizing open-mindedness, empirical analysis, pluralism, a thorough grounding in philosophy and the history of ideas, and a vital concern for contemporary problems—is credited with shaping the intellectual fabric of postwar Norway. At a press conference for Naess's eightieth birthday, the Norwegian Minister of Education testified to the significance of the Norwegian version of Naess's *Communication and Argument*, one of the primary texts for the *examen philosophicum*. "We have all read it. We *still* cheat in argumentation, but now with feelings of guilt."¹⁰

Naess is also credited with rekindling the study of philosophy in Norway and with forming the Oslo school of philosophy. The section on Scandinavian philosophy in *The Encyclopedia of Philosophy* elaborates:¹¹

The philosophical milieu in Norway today [circa 1967] is determined by an internationally known and original philosopher. . . . Arne Naess . . . is the originator of a radical type of empirical semantics and the leader of the so-called Oslo group. . . . The empirical methods applied by the Oslo group employ carefully worked-out questionnaires. By the help of such questionnaires and by teamwork, philosophers of the Oslo group have carried out investigations of such expressions as "truth," "democracy," and "private enterprise." . . . If it is correct that Norwegian philosophy has had a dead period,¹² it is equally correct to assert that, primarily because of Arne Naess, Norwegian philosophy is now in the middle of a period of life and growth.

SERIES EDITOR'S INTRODUCTION

When asked to comment on this passage, Naess was emphatic about inserting an addendum to the last sentence.¹³ He was proud to convey that contemporary Norwegian philosophers pursue a wide variety of directions and employ a diversity of approaches, many independent of Naess's own line. This point is borne out by the more than forty-four permanent teaching positions currently at the University of Oslo's Institute of Philosophy and the broad spectrum of approaches these philosophers pursue, from the analytic tradition to phenomenology and from existentialism to hermeneutics. As one of Naess's successors, Alastair Hannay, in his section on Norwegian philosophy in the *Oxford Companion to Philosophy*, has commented, "Norway enjoys a varied and vigorous philosophical life. . . . Philosophy's place in Norwegian academic life, as in the society at large, is due in large measure to Naess."¹⁴

The reach of Naess's contributions to philosophy and social research extends well beyond Norway. Significant international recognition has also come his way for these contributions. He has received the Peer Gynt Prize awarded by the Norwegian Parliament (2004), the Nature and Environment Prize from the Nordic Council (2002), the Nordic Prize from the Swedish Academy (1996), the Mahatma Gandhi Prize for Non-violent Peace (1994), and the Sonning Prize for contributions to European culture—Denmark's version of the Nobel Prize (1977). He has even been honored by five festschrifts, one each for the occasions of his seventieth, eightieth, and eighty-second birthdays and two for his eighty-fifth birthday.¹⁵ He is the founding editor of the influential journal, *Inquiry*, created to promote collaboration between philosophers and social scientists. He is also a renowned mountaineer and climber, an occasional nonviolent political activist, and father of the deep ecology movement. His social concern, sense of wonder, and trickster nature have all contributed to his success at numerous academic posts around the world—preferably near mountains or deserts—from Berkeley to Jerusalem and Helsinki to Hangzhou. He is, to this day, still a frequent international speaker.

Even with this high level of accomplishment, the significance of his work as a whole—as a gestalt—has yet to receive broad-scale appreciation outside of Scandinavia. There are many explanations for this situation.

The overarching reason has likely been the general inaccessibility of his oeuvre. This inaccessibility has many facets. Naess has been incredibly pro-

SERIES EDITOR'S INTRODUCTION

lific, producing over four hundred publications, more than thirty of which are books. These publications span topics from argumentation theory to zeteticism, with adventures along the way at such seemingly incongruous destinations as climbing ethics, cultural anthropology, and deep ecology. His range of topics—in abundance, breadth, and depth—is trying, at best, for our increasingly compartmentalized and specialized academic communities.

In addition, the bulk of his most significant works have been out of print for quite some time. Many of the earlier editions of the books were edited poorly and documented sparsely. A significant portion of his important articles and book chapters appears in obscure or difficult-to-find books and journals, and much of his work has remained unpublished (at least two hundred papers and several book-length manuscripts). Naess's main works appear in three primary languages, German, Norwegian, and English, although he has also written in Danish, Swedish, and French. Finally, Naess's prose can be dense and opaque, if not downright confusing. Although this trait is by no means unusual for a philosopher, when blended with Naess's appreciation for vagueness and ambiguity, his aversion to authoritative stances, and his tendency to revisit topics by reconsidering earlier viewpoints, the already high entrance fee can become prohibitive.

The boundless range of Naess's interests and the general inaccessibility of his entire oeuvre have led some scholars to view him rather pejoratively as a dilettante. Some of these critics view him as flitting from one area of interest to another, not mining any to its logical conclusion; some see him as throwing away a great talent in logic; some view his social research, especially his work with questionnaires on lay people's and experts' perceptions of philosophical concepts and his use of statistics, as outside the realm of serious, professional philosophy; and still others see him as inappropriately conjoining his philosophy with activism. His breadth has even led a few of the more extreme critics to dismiss his work out of hand. Although some of the criticisms detailed above do have merit, in my view Naess gives the dilettante a good name.

To address this range of concerns, the *Selected Works* project was conceived. The project was the brainchild of Douglas Tompkins. "Miracle Doug," as Arne refers to him, is the founder of the Foundation for Deep Ecology and is himself a renowned climber and kayaker in addition to being a wildlands philanthropist who has helped protect immense tracts of

SERIES EDITOR'S INTRODUCTION

land in Chile and Argentina, some as large as Yosemite. The *Selected Works* would have simply remained a “great idea” without Doug’s generosity and support. The project was initiated in 1994 and commenced editorial work in 1996 under my direction.

In the introduction to his *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, and Sartre* (1968), Naess decries the condition whereby the philosophical life of an individual is set by the local philosophical scene, by provincial biases, or by what is easily accessible.¹⁶ Such accidents of environment should not, in Naess’s view, play a pivotal role in shaping a budding philosopher’s development. I see the *Selected Works*, at least in part, as a response to this predicament.

The purpose of the *Selected Works* is to bring—for the first time—the full scope of Naess’s philosophical contributions to the English-language audience in one collection of highly readable and meticulously edited volumes that adhere to the highest standards of contemporary academic philosophical publishing. The *Selected Works* is, however, by no means exhaustive; it is not a collected works.¹⁷ We have simply aspired through careful selection to offer a representative and relatively expansive collection of Naess’s principal writings. As such, the *Selected Works* is the definitive repository of Naess’s oeuvre, chronicling the development and progression of his thinking for scholars, students, and critics alike.

In the remainder of this essay, I attempt to sketch briefly one possible version of an intellectual biography for Arne Naess. I endeavor to trace some key influences on Naess’s philosophical development, discuss the evolution of his philosophical outlook, and touch on the relevance and significance of each volume in the *Selected Works*. I close with a short note on our editorial approach.

From Scientism to Wisdom: Toward a Philosophy of Life

The philosophic researcher should be task-minded, not discipline-minded,
and should follow his questions wherever they lead.

Arne Naess, “Norway”

Arne Dekke Eide Naess was born in 1912 in the dining room of a large house with a wild, expansive garden. The house was on the outskirts of Oslo in Slemdal, a short walk from where Naess lives today. Arne was the

SERIES EDITOR'S INTRODUCTION

unplanned fourth child of a wealthy family from Bergen. Before he was a year old, his father, who was ill with cancer, had died. Overwhelmed, his mother, Christine, entrusted little Arne to the family's governess. This is where his first memories begin.

Arne speaks of Mina, his governess, endearingly. She is described as satisfying little Arne's every wish, be it procuring live flies for his bath or bringing a trunk filled with bottles on a family trip so that he could continue his water-play experiments. Sometime before Arne was four, Christine dismissed Mina, ostensibly for spoiling Arne too much. This initiated a deep rift between Arne and his mother, which was never to be mended. It also set in place a sense of loss, alienation, and resistance to emotion that profoundly influenced Naess's early personal and philosophical development.

Significantly later, after an intensive six-day-a-week, fourteen-month psychoanalysis with Freud's noted collaborator Dr. Edvard Hitschmann, Naess came to understand his impenetrable shell that keeps others at arm's length (*Panzercharakter*, in Freudian terms) as resulting from a reaction to his mother's unreliability and emotional hysteria. His effort to keep his mother at a distance morphed into a general aloofness and distancing. The adolescent Arne began to favor an "objective," bureaucratic approach to language. He saw art, music, and poetry as being seduced by emotion, by beauty and form, but viewed science and philosophy as realms from which such emotions should be banished. This prejudice would take decades to overthrow. At this time he also developed a single-mindedness and resistance to inconvenience and pain that to this day make it easier for him to concentrate and focus. As Hitschmann pointed out, however, this inward turn has a flip side, a certain self-destructive or masochistic bent that was later to plague him, particularly in his relationships with women and his children.

Much of Arne's early childhood was spent at the seashore, and this is the period in which his interest in nature and experimentation began to flourish. Feeling somewhat distanced in his relations with people, he identified with nature, especially little sea creatures. He waded in shallow water for hours, inventing experiments to test nascent hypotheses about the behavior of small sole, tiny translucent shrimp, and crabs. He describes these experiments as engendering an early enthusiasm for diversity and a tendency to suspend judgment on the nobility or status of different beings. He

SERIES EDITOR'S INTRODUCTION

loved these creatures for their unique qualities and their amusing adaptations and limitations. They inspired a certain egalitarianism, which took hold and later influenced his philosophical approach in profound ways.

Young Arne was restless. He had an early penchant for “collecting” and organizing large groups of numbers, stones, and stamps. He started climbing trees in the family’s little “wilderness” before he was five and soon progressed to big firs and spruces. He found that he enjoyed being able to watch people from above. Arne outgrew trees fast. His desire for perspective and the opportunity to survey broad areas was rapidly transferred to mountains. At the age of five, he began going to his mother’s small mountain cottage in the town of Ustaoset, high in the Hardangervidda between Oslo and Bergen. By the age of eight, he had adopted Hallingskarvet, a bread-loaf-shaped mountain about three and a half hours’ walk from Ustaoset, as his surrogate father. In his teenage years, this obsession for expansive perspectives translated into a lifelong passion for mountaineering. When Naess was sixteen or seventeen he climbed the 106 tallest mountains in Norway. It was around this time that he was first introduced to Spinoza’s *Ethics* by a Norwegian Supreme Court justice that he met in the mountains. Naess’s desire for a broad and open perspective, for seeing things in totalities (god’s-eye view), translated to his studies. Young Naess read widely in economics (especially value theory), science, philosophy, history of philosophy, and the Earth’s biological history.¹⁸ This commitment to cultivate an ever-expanding perspective would later potentially influence his approach to philosophy.

Arne’s youth was spent captivated by piano, study, and mountains. His decade-older brothers took it upon themselves to toughen up their timid younger brother, as well as introduce him to the ways of the world and scholarship. When Arne was only eight, his eldest brother, Ragnar, left for America to study for a Ph.D. in chemistry at MIT. Ragnar later went on to receive one of the Harvard Business School’s first degrees and became a successful stockbroker in the United States. Erling studied economics and went on to create an international shipping empire; he became famous for his assistance to the Norwegian government-in-exile during the Nazi occupation. His sister, Kiki, married a German doctor and after the Second World War returned to Norway to become a physical therapist. From Kiki he learned the power and significance of offering encouragement to others.

SERIES EDITOR'S INTRODUCTION

During his early years and well into adulthood, Arne's tight-knit relationship with his siblings provided security and support for him to "find his own way" — *sva mārga*, to use one of his favorite Sanskrit terms. Although he tended not to seek their financial assistance, his wealthy and generous brothers offered a sense of comfort, safety, and the occasional extravagance, which in later life made it easier for him to live his bon mot, "simple means, rich ends."

Naess studied philosophy, mathematics, and astronomy at the University of Oslo. At nineteen, after completing the equivalent of an undergraduate degree, he left Oslo to continue his studies in Paris. Naess was put off by the adoration Bergson received in Paris, but ultimately left to seek broader vantage points, cheaper living, and better climbing opportunities. After completing two master's theses at twenty-one, one exploring discussion about the concept of truth and the other exploring the use of behavioral psychological principles to judge truth validity, Naess left Oslo again, this time for Vienna. In Vienna he took master classes in piano, where, following his trickster nature and as a response to the strict taskmaster Fuchs, he "learned" new material. When he ran out of pieces he had long since mastered, he quit. Thinking that it was necessary for philosophers to have high levels of self-knowledge, he underwent intensive psychoanalysis with Dr. Edvard Hitschmann. As a part of that process he assisted with the treatment of patients in a psychiatric hospital and developed tremendous empathy for the suffering of humankind. While in Vienna, he was also warmly welcomed at the famous Schlick seminar.

The logical empiricists' friendly, equiminded approach to discussion made a great impression on Naess, but he was not equally affected by their ideas.¹⁹ The young Arne was impressed by the preciseness, empirical nature, and lack of emotion in science—he wanted to practice philosophy with a scientific bent and he wanted to test philosophical hypotheses with experiments. He was already interested in perennial philosophical problems and did not believe that most of them were ultimately pseudoproblems that could be solved by investigating inconsistencies in language. His most significant philosophical issue with the logical empiricists was not that they were empirical, although he believed they were misguided in thinking that any philosophical problem could be wholly empirical, but that they were ultimately antiempirical in their belief that a logical gram-

SERIES EDITOR'S INTRODUCTION

mar of language was more suitable for investigating the use of terms than statistical analysis of their actual use. Naess's detailed critique of the logical empiricists' position and reflections on his personal experiences attending the Schlick seminar appear in volume VIII. In this critique, Naess expresses a concern that in their interpretation of terms, many philosophers (not just the logical empiricists) were artificially constricting the range of possible interpretations and thus unintentionally reducing potential insights regarding the diversity of tenable positions on problems of vital concern. This perspective presaged his later views, particularly those expressed in *Interpretation and Preciseness* (SWAN I), and his later approach to cultural anthropology and philosophy of science. Naess sums up his general perspective on the state of philosophy at the time with the following remark: "The turn of (Western) philosophy in [the twentieth century] towards language rather than cosmos, towards logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind-alley."²⁰

While in Vienna for fourteen months in 1934 and 1935, Naess made final revisions to his doctoral thesis, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior).²¹ Although Naess drew inspiration early on from Russell and Whitehead, his doctoral thesis can be seen, in part, as support of the American Pragmatists (James and Dewey) in opposition to Russell and early Wittgenstein. According to Dewey, the main purpose of his philosophical writings was "to reintegrate human knowledge and activity in the general framework of reality and natural processes."²² Naess did just this by creating a radical and unique approach for exploring how high science is performed, a sort of science of science. At this point, Naess believed it was possible to use such an approach to obtain a complete account of all science within one system. Inspired by the ethologist Uexküll's "special biology" (*Umweltforschung*), Tolman's "objective" behavioral psychology ("molar" behaviorism), and the cultural anthropologist Malinowski's work on speech and nonverbal behavior, Naess took on the standpoint of a neutral, nonparticipant spectator and outlined a program for an empirical metascience of science, an ethological approach to epistemology of science.

Naess used the idea of a dispassionate visitor from another solar system coming to study Earth-based scientists to demonstrate the possibility of completely describing both the activity of researchers and the contents of

knowledge without drawing on the subjective models that governed traditional epistemology and presupposed knowing subjects or minds. The idea was to study or rather “witness” science similar to the way experimental psychologists study rats, but without falling into the trap of imposing their own experience of reality and their preexisting conceptual models of reality (“maze epistemology”), or their scientific pretensions. In the view described in *Erkenntnis*, knowledge is cognition—it is an activity with intention—and this helps to dismantle the subjectivist dualism between the content of knowledge and the activity of research. Naess’s interest was in describing these patterns of research activity. He argued that the *terminology* associated with scientific activity—which is bound to the subjective-reality model—changes in leaps and bounds, not the *patterns of research activity*, which are in constant, but gradual, flux. With this argument that change in science happens gradually, by generalization and differentiation, Naess foreshadowed his response to Kuhn well before *The Structure of Scientific Revolutions* was published in 1962.

With *Erkenntnis*, Naess also anticipated ideas that later became prominent in linguistic philosophy, such as the importance of ordinary language over formal systems and the importance of using observation of contrasts and discriminations to build up understanding of systems. In the end, presaging his own radical pluralism to come, Naess seems to relax his early position on the importance and possibility of creating a metascience of science from the “far outside” and ultimately comes to view subjective and behavioral models as two different point-of-departure formulations in an indefinite plurality of equally valid approaches for a metascience of science. This refined perspective is taken up in Naess’s 1965 article “Science as behavior” (in SWAN IX), which returns to the prospects and limitations of creating a behavioral metascience to study the scientific enterprise, but this time from the “near outside.”

At age twenty-four, after receiving his Ph.D. from the University of Oslo for his work on science as behavior, Naess returned to his interest in the problem of truth. A particular concern was the inadequacy of philosophers’ intuitive methods for capturing how lay people conceived and used the term *true*. In 1937 and 1938 he developed and tested an empirical approach for using questionnaires and statistical analysis to investigate non-philosophers “commonsense” views on the notion of truth. He then related

SERIES EDITOR'S INTRODUCTION

these notions to philosophers' theories of truth. Naess found an amazing diversity of views among the amateurs. He also found that their views, although typically devoid of philosophical pretensions, generally covered the views represented by professional philosophers. This work elicited substantial controversy, most of which came from philosophers who viewed it as undignified to use questionnaires and statistics to investigate one of the great problems of humanity. Naess's results were published as *"Truth" as Conceived by Those Who Are Not Professional Philosophers* (1938). A summary of this work is presented in Naess's "Common Sense and Truth" (in SWAN VIII). Naess's continued application and refinement of these techniques would evolve into empirical semantics.

In 1937 Naess fortified his lifelong fascination with the arctic climate Hallingskarvet by building Tvergastein, his now-famous rustic and remote hut, at its base, a three-and-a-half-hour trek from the train station at Ustaoset. He outfitted the hut with Rube Goldberg oil lamps that also served as stoves for warming tea and with an eclectic library of teach-yourself language manuals, Sanskrit-English dictionaries, astronomical and wildlife field guides, novels by Dostoyevsky and Ibsen, letters of Spinoza, and a complete philosophy library. Following his passion for amateur science he also created "institutes" of petrology, chemistry, zoology, hydrology, and botany at Tvergastein. Naess has written the bulk of his work at Tvergastein and spent the equivalent of about twelve of his ninety-two years living there. The enormous open views at Tvergastein afforded Naess the distance and perspective he so craved while insulating him from philosophic fashion and dogma. Here he had the luxury, freedom, and good fortune to pursue his own interests free from the banalities and distractions of academic life. After completing what is now Tvergastein's main room, Naess went on to perform postdoctoral research at Berkeley (1938–39) with the pioneer of empirical psychology, E. C. Tolman. At Berkeley, he went from studying the behavior of rats faced with many possible alternatives to studying the behavior of the scientists studying the rats.

Naess returned to Oslo in 1939 to be appointed to the University of Oslo's Chair of Philosophy at the age of twenty-seven. On April 9, 1940, German forces invaded Norway; it would remain under Nazi rule for the next five years. This was a harrowing time for academics throughout Europe. Arne tried to maintain his unruffledness, pouring himself into re-

SERIES EDITOR'S INTRODUCTION

search and curricular reform initiatives intended to widen and expand the perspective of university undergraduates. He tried to stay at Tvergastein often, and this afforded him some peace and solace in a world of great tension. Before long, however, even he was drawn into the resistance movement. In the fall of 1943 he played a central role in foiling a Nazi attempt to deport University of Oslo students to concentration camps for “reeducation.” The University was subsequently closed and Naess became even more committed to the resistance movement and his research. By this time he had developed great admiration for Gandhi’s catalytic 1930 *satyāgraha* campaign, the march to Dandi in protest of the British salt tax. Naess was greatly impressed with Gandhi’s idea of trying to meet one’s opponent in a manner that would calm passions and facilitate truthful communication. He thought such an approach could have had a significant effect on quenching the Nazi expansion, *if* the necessary infrastructure to support *satyāgraha* had been created in European countries. After the war, Naess used these insights in his efforts to bring together suspected torturers and the families of torture victims to gain a sense of closure on the fate of their loved ones—and to avoid having the “traitors” subjected to equally horrid persecution. In 1948 Naess was invited to be the scientific leader of a new UNESCO project created to explore ideological controversies between the East and the West. He was soon off to Paris again, this time to pursue his interest in using philosophy to address questions of social and political importance.

The Cold War was a tinderbox and two core ideological conflicts revolved around use of the terms *democracy* and *freedom*. Naess was asked to address both but countered that UNESCO’s requirement that he deliver a report within one year made it essential for him to consider *democracy* first. His goals were to clarify what people mean when they use the term *democracy* and to understand the causes of ambiguity and confusion that result from its use. After an extensive literature review, which chronicled historical usage of the term, Naess and his assistant, Stein Rokkan, prepared a thirty-question survey that was distributed to almost 600 international experts in the fields of philosophy, law, history, political science, sociology, economics, communications, and logic. Naess used the roughly 100 replies to create an empirical study of “agreements” and “disagreements.” The study demonstrated *democracy*’s richness, diversity, and multiplicity of

SERIES EDITOR'S INTRODUCTION

meanings and thus undermined its misuse in both the East and the West. This incited detractors from every ideology, who roundly criticized the resulting report, *Democracy in a World of Tensions*, which according to Naess “was promptly sold out and never reprinted by UNESCO due to the politically dangerous character of its items.”²³ Naess’s “Analytical Survey of Agreements and Disagreements,” along with two other pieces on ideological convictions and rationality, appears in SWAN IX.

The UNESCO democracy study was the first and last international, large-scale application of Naess’s empirical semantics approach. He was originally interested in doing another study on “cultural diversity,” but neither this nor the “freedom” study came to fruition. Naess learned—much to his chagrin, and as his superiors had warned—that UNESCO was a place for writing reports; it was no place for conducting research. Naess’s frustration with the UNESCO experience and his wanderlust for the perspective of mountains led him to daydream first, and then to “pursue non-essentials”:²⁴

The arguments against abandoning the imaginary joys of the Himalayas for an actual expedition seemed strong to me, and so they still do. But in the autumn of 1948 the longing for the mountains pushed aside all sensible considerations. For the first time since I was twelve years old, I had to do without a summer holiday in the mountains. The safety valve guarding one against exaggerated climbing expeditions was thus removed. Added to this came the great disappointment in my own work. Lured by UNESCO’s plans of philosophical research into international ideological conflicts, I had been tied up in Paris for nine months. Such large-scale extravagant schemes prove, however, impracticable. Too much nationalism and too little belief in research prevented UNESCO from getting the number of nations to subscribe to such long term schemes. By the way of compensation, I indulged at night in delightful trips to the Alps. As the situation got worse, this was, however, not sufficient compensation; the material was exhausted. Then my fantasies took me to the Caucasus. Later I had to go all the way to Persia, Afghanistan, Hindu Kush and India, and so I was committed.²⁵

Although Naess’s research interests and total view continued to evolve after 1953, the general philosophical approach of the mature Naess, outlined at the beginning of this essay, was basically in place. Naess has described his

philosophical work as falling into four periods or phases. From the mid-1930s until about 1940, he focused on philosophy of science. Then until about 1953, he concentrated on empirical semantics. A short period, surrounding the publication in 1968 of his major work on the zetetic scepticism of Pyrrho, ends when, at the pinnacle of his philosophical career, he sought early retirement in 1969 to devote himself more fully to ecological issues and activism. Naess has commented that this effort to be more actively engaged in social and political conflicts reflects his desire "to live rather than function." This view adequately reflects coarse, general trends, but it fails to do justice to Naess's philosophical approach, which has him mine a larger range of topics and return to them in a helical fashion throughout his life. I would rather describe his work as falling into thematic areas that were picked up, sometimes put on ice, but returned to periodically throughout his life. Although I concur that the period after his formal retirement can be seen as emphasizing ecological philosophy and activism, the two decades between 1960 and 1980 also represent a period of considerable productivity on conventional academic philosophical topics. It was in those decades that Naess produced important work, especially, on scientific and cultural pluralism, Gandhi and Spinoza scholarship, history of philosophy and philosophy education, and normative systems theory. He has written on a wide range of important philosophical topics even into the 1990s and beyond, during which time he produced, among other works, his *Life's Philosophy* (2002; coauthored with Per Ingvar Haukeland), introductions to the philosophy of Gandhi (2000) and Spinoza (1999), and *Introduction to General Relativity and Its Mathematics* (1998; coauthored with Øyvind Grøn).²⁶ An adequate sketch of Naess's subsequent research interests and philosophical development can be gleaned from the following brief discussion of the volumes in the *Selected Works* and the discussion, at the end, of how his earlier work figures into the evolution and exegesis of deep ecology.

Naess's best-known philosophical work is likely *Interpretation and Preciseness*, published in 1953 (SWAN I). It is an attempt to convince the world of analytical philosophy about the types of approaches that are necessary, from the standpoint of a radical empiricist, to adequately interpret terms and point-of-departure statements (T_0 statements), given the manifold of plausible interpretations. It highlights the role and potential of experience in relation to intuition and reflection by requiring that every direct or im-

SERIES EDITOR'S INTRODUCTION

plied hypothesis regarding the actual use of terms, phrases, or sentences be testable. In addition, it responds to the ostensibly antiphilosophical sentiment in *Erkenntnis* by clarifying the function of and relationship between point-of-departure statements and precizations. In Naess's semantics, the most general statements, T_0 statements (words or sentences), are phrased in ordinary language and are intended to be philosophically neutral. T_0 statements serve as points of departure for investigations of possible interpretations. When a new interpretation of an expression eliminates some of the ambiguity of a preceding interpretation, without adding any new ambiguity, it is said to be a "precization." Thus, a sentence T_1 is more precise than a sentence T_0 when every plausible interpretation of T_1 is also a plausible interpretation of T_0 but at least one plausible interpretation of T_0 is not a plausible interpretation of T_1 . This process of using successive differentiation to better understand people's interpretations of terms, phrases, or sentences can go on almost ad infinitum; it is limited only by time, resources, imagination, and willing test subjects. With this process, however, Naess has created a formal approach for classifying different statements (interpretations) based on users' "depth of intention," the point at which they no longer, explicitly or implicitly, accept or embrace higher levels of precization. A focal point is Naess's approach of directly employing surveys to explore systematically and empirically the meanings of terms, phrases, or sentences based on their occurrences. Naess also created a formal procedure for comparing occurrences, both interpersonal and intrapersonal, that involves performing tests for different forms of synonymy. Naess has applied his empirical semantics approach to explore the meanings of "truth," "democracy," "it is the case," "certain," "perfectly certain," and "extremely probable" (see SWAN VIII for additional details on and applications of empirical semantics).

In *Scepticism* (SWAN II), published in 1968, Naess takes on the generally accepted position that scepticism, if widely embraced, leads to the intuitively false conclusion that we cannot know anything. Naess explores the variety of historical interpretations of scepticism in light of Sextus Empiricus's outline of Pyrrhonian scepticism. Three categories of philosophical positions on the question of truth are considered: Dogmatists claim at least one truth, Academicians negate the possibility of finding any truths, and Pyrrhonists neither assert that they have found any truths nor assert the impossibility of finding one. Naess takes a sympathetic view of this last

group, arguing that this form of zeteticism can represent both a viable philosophical position and a way of life that supports positive mental health. What ultimately sets this position apart is not that supporters are fundamentally opposed to making acts of assertion, to stating that "something is the case," but that they do not make such assertions with the conviction of truth. Naess also uses empirical semantics to demonstrate support for this position on rational and epistemological grounds. Distinguishing between one's philosophical view and the necessity of firm, socially responsible action in everyday life, he also responds to the common notion that this radical nondogmatism generally leads to paralysis of action. In the end, Naess argues that adopting this updated view of Pyrrhonic scepticism could lead to quite the opposite, a more open-minded approach to philosophy and life. Further elaborations on particular aspects of Naess's Pyrrhonism along with a response to Rescher's reappraisal of scepticism appear in SWAN VIII.

Which World Is the Real One? (SWAN III), which was first published in 1969 and revised in 1982, is, in part, an attempt to reinvigorate appreciation and study of the broad variety of philosophical outlooks and total views that exist in Chinese, Indian, Greek, Western, comparative, and recent philosophy. It makes use of Naess's empirical semantics, developed in *Interpretation and Preciseness*, to argue that it is an illusion to assert that combined scientific and philosophical or "purely" philosophical syntheses of such total views can exist. Naess argues that the results of science cannot be integrated into any single world picture, in part because such attempts at synthesis are necessarily fragmentary and because valid multiplicities of syntheses exist. He also takes up the question of the comparability of total views. Such comparisons, although important, are inevitably shaky because, despite admirable aspirations for standing back to obtain a meta-perspective, real people can never totally throw off their own total views; regardless of how explicit those views may be or of how conscious of them their holders are, biases are unavoidable. We always have our own perspective to contend with. For Naess the inevitable conclusion is that pluralism is inescapable and nothing to lament. He combines these points of view with a discussion of cultural anthropology to argue for the critical importance of supporting the flourishing of rich cultural diversity. Additional articles elaborating themes related to the significance of maintaining cultural diversity and its relationship to ecological sustainability appear in SWAN X.

In *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN

SERIES EDITOR'S INTRODUCTION

IV), published in 1972, Naess suggests that scientific theories must be understood in the wider context of the plural rationalities from which they spring. Science is not autonomous. Nor can it be seen justifiably as arising independently from the general enterprise of building philosophical systems. Furthermore, the relationship of models to reality is always indirect. This volume should be seen as an effort to erode the popular misconception of science as infallible and a viable surrogate for religion, not as an attempt to build a unified theory of science within one system, which Naess had long since rejected. Because no theory can ever be either fully verified or falsified, there exists a significant freedom of choice in both modes of exploration and theories that one can tentatively adopt. The notion of “fundamental theories” is immediately called into question. As the undemonstrated (and often undemonstrable) assumptions upon which theories rest are changed, a huge multiplicity of possibilities for future theory development arises, thus possibly helping to inspire a renewed enthusiasm in science by broadening our concept of rationality and restoring the role of imagination. Articles extending or elaborating on the ideas in *The Pluralist and Possibilist Aspect of the Scientific Enterprise* appear in SWAN IX.

Naess's third book on Gandhi, *Gandhi and Group Conflict* (SWAN V), was published in 1974. This book develops an intellectually rigorous presentation of the theory of *satyāgraha*—the way of militant nonviolent resistance—as a strategy for conflict resolution. This work is a paradigmatic example of Naess's approach to research and writing. As the eminent Norwegian social scientist and peace researcher Johan Galtung has suggested, Naess's 1955 *Gandhis Politiske Etikk* (Gandhi's political ethics)—with Galtung—and his 1965 *Gandhi and the Nuclear Age*, along with his articles that analyze or extend on Gandhi's work (see SWAN IX and X), act as exercises or drafts for this, his major work on Gandhi.²⁷ Using Gandhi's own recorded accounts, Naess explores the norms and hypotheses tacitly employed by Gandhi in his nonviolent campaigns and then uses these to create the first philosophical and logical systematization of Gandhi's approach to militant nonviolence. A careful investigation of Gandhi's two ultimate norms (as interpreted by Naess), “Seek complete self-realization” and “Seek truth,” and his belief in *advaita* (nonduality), along with a consideration of their parallels to Spinoza's unity thesis, will reveal interesting insights into Naess own characterization and use of “Self-realization!” as

the single ultimate norm of his Ecosophy T. Naess also considers Gandhi's approach to nonviolent conflict resolution in light of contemporary reactions against the use of nonviolence by Frantz Fanon, Malcolm X, Stokley Carmichael, C. V. Hamilton, and Sartre. He then examines Gandhi's ideas and intentions regarding group conflict in light of the ideas and intentions underlying other modern philosophies of conflict, including those of Luther, Nietzsche, Tolstoy, and Jaspers.

In *Freedom, Emotion, and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics* (SWAN VI), Naess uses symbolic logic to present a formalization and partial reconstruction of a small but important part of the *Ethics*. Spinoza's system is embedded in the seventeenth century and expressed in Medieval Latin. Two of Naess's goals are to bring empirical analysis to bear in trying to interpret and update Spinoza's system and to make Spinoza's insights more accessible and relevant to contemporary readers. To perform his reconstruction, Naess draws heavily on a small book he produced in 1962, *Equivalent Terms and Notions in Spinoza's Ethics*, which lists and discusses 243 equivalences that are directly asserted or suggested by Spinoza in the *Ethics*, according to Naess.²⁸ Accepting the transitivity of the equivalence relations as a general rule, Naess argues that a vast array of structural relations can be elucidated (many of these are often only suggested or implicitly asserted by Spinoza). One of Naess's key conclusions is that every living thing is to some extent "in itself" and to some extent "in something else" due to the presumed gestalt nature of reality. Another is that the terms *substance*, *attribute*, *God*, *mode*, and *Nature* are "expendable"; Spinoza's basic nondualism is made clearer by Naess. A third conclusion is that *to be active* and *to understand* cannot be systematically distinguished in the *Ethics*. This notion, which has important implications for philosophy of science, is also embedded in Naess's conclusion in *Erkenntnis* that knowledge is cognition—the content of knowledge and the activity of research cannot be cleanly separated. Naess uses his analysis to explicate three main themes of Spinoza's system: the importance of a notion of uncoerced freedom (not coerced by externals), the importance of developing and acting on strong emotions to make progress in achieving higher levels of freedom, and the importance of joy that activates the complete person (as opposed to joy that simply activates part of the body or the soul). By clarifying the semantic structure of a central part of the *Ethics* with his own logical struc-

SERIES EDITOR'S INTRODUCTION

ture, Naess explains that there exists a wide variety of possible interpretations of the contents of the *Ethics*. Articles on Spinoza's determinism and its relationship to freedom, Spinoza and Māhāyana Buddhism, "Spinoza's Finite God," and other Spinoza-related topics appear in SWAN IX. Articles that explore Spinoza as an inspiration for deep ecology appear in SWAN X.

The English translation of *Communication and Argument: Elements of Applied Semantics* (SWAN VII), which was first published in 1966, is largely a popularization of the central ideas in *Interpretation and Preciseness*. The English edition is a somewhat watered-down version (no exercises) of the Norwegian edition that from 1941 to 1969 was used by nearly 100,000 university students in the *examen philosophicum*. Its purpose, to quote the *Times Literary Supplement*, is " . . .to teach people in a democratic society to think clearly, coherently, and above all responsibly." Naess's hope is that teachers use controversial examples from current events—the more emotional the better—to confront students with their own confusion and encourage them to strive for higher levels of depth of intention. The final chapter outlines six "Gandhian" rules of effective discussion, which emphasize avoiding six forms of "irrelevance in discussion."

The first two volumes of selected papers (SWAN VIII and IX) contain important material that is not covered by the preceding volumes, material that complements them, or material that builds on or reevaluates positions taken earlier. Volume VIII includes sections on "Empirical Semantics and Truth," "Zeteticism," "Empiricism, Possibilism, and Pluralism," and "Metaphysics, Morals, and Gestalt Ontology." Volume IX includes sections on "Democracy, Ideology, and Rationality," "Philosophy of Science," "The Philosophy of Peace, Gandhian Ethics, and Communication," "Spinoza," and "Philosophical Development, Environment, and Education" (which includes an autobiographical article describing key influences in Naess's philosophical evolution, "How My Philosophy Seemed to Develop" and an interview, "Deep Ecology and Education"). A number of the especially significant articles have already been referred to, where relevant, in the discussion of Naess's philosophical evolution; other articles are discussed in the notes.

Today, Naess is, perhaps, best known for his "deep ecology" writings, the topic of *Deep Ecology of Wisdom* (SWAN X). This work began with a short unpublished paper written in 1965, "Nature ebbing out" (in SWAN X), and continues to this day. As the primary architect of deep ecology, Naess has

more than seventy-five published articles and book chapters and more than sixty unpublished pieces on this topic. His only book-length discussion of deep ecology began with a short mimeograph, *Økologi og Filosofi* (Ecology and philosophy), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi, Samfunn og Livsstil* (Ecology, community, and lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. This book has not been included in the *Selected Works* because it is widely available and currently in print.

Volume X is the first comprehensive collection of Naess's work on deep ecology—it includes a broad array of articles on its history, influences, theory, development, practice, and prospects. This volume shows how deep ecology represents the integration and culmination of Naess's lifelong interests in philosophy, social research, activism, science, and nature. It demonstrates how Naess, in his explication and elaboration of deep ecology, draws extensively from both his life experience and his research on empirical semantics, scientific and cultural pluralism, Pyrrhonic scepticism, Spinozistic nondualism and activeness in relation to problems, gestalt ontology, normative systems theory, total views, and Gandhi's concepts of self-realization and nonviolent communication. Volume X also shows how Naess's approach to deep ecology has unfolded over time, with substantial emendation, in part as a response to the worsening ecological crisis, in part to answer criticisms that deep ecology was turning into a cult or religion, and in part to address the considerable confusion and controversy that arose from his use of provocative terminology and philosophical vagueness.

Ever since he coined the term *deep ecology* with his now famous paper "The shallow and the deep, long-range ecology movement: A summary," (in SWAN X) given at the 1972 Third World Future Conference in Bucharest, Naess's central concern has been to use philosophy and philosophical thinking to help humans overcome the ecological crisis and, ultimately, to restore the Earth to a state of rich and flourishing biological and cultural diversity (see volume X). A basic premise is that some ethical norms, particularly those grounded in spontaneous experience, can be tentatively accepted as objectively valid. An example for Naess would be the statement that "Every living being has an equal right to live and flourish, *in principle*." This statement in no way denies that maintaining our existence necessitates killing living beings. Another key premise is that the human potential for caring is not static or

SERIES EDITOR'S INTRODUCTION

limited—it can be both extended and deepened. The ecological crisis is embedded in an ecocultural crisis. Its resolution will necessitate cooperation and collaboration among the peace, social justice, and ecology movements.

Naess does not see himself as “inventing” deep ecology. Rather, he gave a name and a philosophical framework to a minority tradition, a nascent social movement that has been with humanity since at least Buddha, Chuang Tzu, Saint Francis of Assisi, Thoreau, John Muir, and Aldo Leopold, and is epitomized by Marjory Stoneman Douglas’s 1947 *Everglades: River of Grass* and subsequent crusade to save the Everglades.²⁹ This movement finally came of age in the contemporary era after Rachel Carson’s *Silent Spring*. Naess’s work on “deep ecology” can be subdivided into three main thematic areas.³⁰

What I refer to as Naess’s deep ecology approach (deep ecology as an ecophilosophical approach) represents his contributions to deep ecology theory—it is essentially an outline of a general philosophy of life, which draws considerable inspiration from Gandhi and Spinoza. The focal points are encouraging ultimate beliefs that support our capacity to identify with all living beings and Naess’s general, pluralistic, normative systems-based strategy for assisting individuals in the process of weaving their ultimate beliefs, descriptive and prescriptive premises about the world, ecological science, and philosophy into systematic conceptual structures for relating to the world—ecologically inspired *total views* or *ecosophies*.

His work characterizing and supporting deep ecology as an international, grassroots social and political movement, along with his work entering into the fray, addressing conflicts, implications, and practical applications of the theory, falls into the realm of contributions to the “deep ecology movement.” Supporters of the deep ecology movement are not united by a commitment to deep ecology as an academic ecophilosophy (which they may not be familiar with or embrace), but by their willingness to endorse the eight-point deep ecology platform, prepared by Naess and Sessions in 1984.³¹ Finally, work discussing his personal systematization of a deep ecological total view falls into the realm of “Ecosophy T.”

Naess coined the terms *deep ecology* and *shallow ecology* in 1972 to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis. In proposing the deep/shallow contrast, he made a technical semantic distinction directed at our level of problematizing—the extent to which we can, and do, coherently and consistently trace our views, practices, and actions back

SERIES EDITOR'S INTRODUCTION

to our ultimate beliefs or bedrock assumptions. Naess starts with a premise, which he has investigated empirically, that at the level of their ultimate beliefs, people generally identify with and appreciate nature. He then uses this to argue that many regrettable environmental decisions are made in a state of "philosophical stupor," in which narrow concerns are confused with, and then substituted for, more fundamental ones.

The "shallow," currently more influential approach to environmentalism is identified with treating the symptoms of the ecological crisis, such as pollution and resource degradation. This reform-oriented approach is grounded in technological optimism, economic growth, and scientific management, not in ultimate premises that plumb the relationship between people and nature. It thus ultimately fails to address the philosophical, social, and political roots of the ecocultural crisis.

The "deep" approach, on the other hand, while in no way discounting the exigency of addressing pollution and resource degradation, adopts a broader, long-term, more sceptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach's proposed solutions take into consideration the nature of reality and the complexity of the problems its adherents hope to rectify. Stressing the importance of addressing the fundamental roots and coevolving causes of the ecological crisis, deep ecology posits that along with humans' special capacities for reason and moral consciousness come special responsibilities, particularly in relation to the flourishing of nonhuman life and the ecocultural sustainability of the planet.

The deep ecology approach calls for expanding our sphere of concern to all living beings—charismatic or dull, gargantuan or tiny, sentient or not. It acknowledges that every living being has value in itself and views the flourishing of nature and culture as fundamentally intertwined—as part of one reality. This *wide-identification* is characterized by the perception that all life is interdependent; common goals bind all living beings to the life process. In Naess's view one can arrive at wide-identification by drawing on a broad diversity of philosophical or religious ultimate premises, with roots ranging from Christian Stewardship to the Gaia Hypothesis to Naess's own ontologically inspired "Self-realization!" In its most expansive form, wide-identification is the intuition that nature's interests and our own coincide, as with Naess's "Self-realization!"—something akin to a blending of the

SERIES EDITOR'S INTRODUCTION

Hindu *ātman* with a biospherical Pareto-optimality principle. Simply stated, this principle asserts that the increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other individuals or species.

By juxtaposing these two, almost caricatured perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The central premise is that society's potential to overcome the ecological crisis rests on guiding discussion and debate to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and their actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an individual's actions and his or her fundamental beliefs, while possibly engendering serious ancillary conflict along the way, will ultimately generate progress toward ecocultural sustainability.

Naess contends, as I have pointed out earlier, that humans act as if we have total views whether or not we make such structures explicit. Because our decisions regarding society and nature are guided by our total views, Naess maintains, we *should* attempt to articulate them. By making these structures explicit, we expand both our opportunities for fruitful debate and interchange and our possibilities for creating policies that are consistent with our collective ultimate beliefs. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending "rights" to certain nonhuman life-forms or grading intrinsic value. The ontologically inspired deep ecology approach attempts to counter the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudo-rational thinking.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of "depth." In the context of deep ecology as an ecophilosophical approach, depth refers to both the general level of problematizing we employ in seeking out the underlying, co-

evolving causes of the ecocultural crisis and the extent of our willingness to consider an expansive array of social and policy responses, even if they necessitate changes that constitute a radical departure from the status quo. Rather than calling for a new environmental ethic or a radical change in fundamental values, Naess's approach to ecophilosophy centers on transforming practice and policy by challenging us to develop more thoroughly reasoned, consistent, and ecologically inspired total views. This work represents a culmination of his effort to integrate reason and emotion. He has created the foundation for a new and promising human/nature relationship that positions humans as plain citizens with special abilities and unique responsibilities and nature as mentor, measure, and partner rather than servant. The current state of global ecological unsustainability has made Naess state that he is optimistic about the twenty-second century but pessimistic about the twenty-first; humans have a long way to go.

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of being inherently fascist, antihumanist, antifeminist, and against having indigenous peoples share wilderness areas with nonhuman life-forms.³² As the articles in volume X will show, none of these criticisms are compatible with a sophisticated reading of Naess's writings on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has clear answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not, on first principles, embrace wide-identification? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that lead to long-term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable means? Third, how can deep ecology help resolve conflicts in environmental decision making when those conflicts result not from pseudorational thinking but from genuine value conflicts?

Throughout this essay, I have tried to show how Naess's life of rich and varied spontaneous experiences and internal tensions have shaped not only

SERIES EDITOR'S INTRODUCTION

who he is as a person, but also who he is as a philosopher. Viewed separately, Naess's contributions to academic philosophy, social research, and ecological philosophy and activism can appear discordant, dilettantish, and incoherent. When, through careful study of his helical progression, his philosophical and personal maturation, the pattern of the whole unexpectedly reveals itself as a unity, the whole suddenly becomes much more than the simple sum of individual books and articles. With the distance of a meta-perspective, Naess's collective philosophical contributions can be seen as a mosaic—as a superordinate gestalt, in some sense, as a rich and inspiring, but inevitably fragmentary total view. Naess has breathed life back into the study of philosophy by turning its study back to life. With his cultivation of a meta-perspective, a whole, new (old) approach to philosophy and way of seeing the world emerges. This richly patterned mosaic, by encouraging us to celebrate our freedom and affirm life, can help us to reshape our relationship to each other and the Earth in new and promising ways.

Conclusion

It was only as a professor that I became aware of the difficulties of suppressing the significance of the development of feelings in human affairs while at the same time worshipping reason. Both are constantly needed.

Arne Naess, *Life's Philosophy*

The ten volumes of this series (along with a subsequent volume of conversations between Naess and myself on deep ecology and his philosophy) make available for the first time access to the breadth and depth of Naess's philosophical thought. Efforts to judge the significance of Naess's philosophical oeuvre—assertions made in the first sentence of this essay—can now be taken up on an informed basis. When embarking on this process, it may prove beneficial to reflect on Henry Adams's insight on the fundamental limitations of communication, and especially the limits of communicating one's fragmentary total view, "No one means all he says, and yet very few say all they mean, for words are slippery and thought is viscous."³³ Spinoza ends the *Ethics* with the following remark: *Sed omnia praeclara tam difficilia, quam rara sunt* ("But all very clear things are as difficult as rare").

In *The Radical Spinoza*, Wienpahl translates the phrase more literally

than usual, rendering *praeclara* as “very clear” rather than the typical “excellent.”³⁴ The quest for clarity is painful and difficult as well as amaranthine. The alternative, however, is to abandon joy and freedom and thus meaning. This is the essence of Naess’s distinction between being an *academic philosopher* and being a *philosopher of life*, between merely *functioning* and *living*. Drawing inspiration from Spinoza, Naess has cultivated a practice of both integrating reason and emotion *and* transforming negative emotions into positive ones. His challenge is before us and the frontier is long—the choice, however, is ours.

Editorial Approach

Naess has always written books as if they were exercises for himself, tentative formulations that chronicled his views at that very second but were always subject to change. As I indicated previously, many of the prior editions of his books were poorly edited and sparsely documented. Existing bibliographies were incomplete, and indexes (in the rare cases in which they existed) were always inadequate. Quotations were often transcribed incorrectly and ill-referenced. In addition, the breadth of his work was enormous and sometimes repetitive. Arriving at a plan for a representative *Selected Works* that would have a consistent format and design was no easy task.

All the selections for the *Selected Works* were made in close consultation with Naess. I would prepare recommendations from my master bibliography file and then, whenever we disagreed, we would discuss the pros and cons of the piece and whether it was appropriate for inclusion (this approach proved particularly helpful when we reached the *Selected Papers* volumes). We immediately made a decision to exclude works that were widely available and currently in print. Other important works, such as his dissertation, and his major work on lay people’s conception of truth, his work on the semantics of democracy and ideological controversy, and his contributions to history of philosophy were more difficult to exclude, but the nature of the project as a selected works demanded such tough choices. I was encouraged by the fact that Naess often published articles that summarized or updated earlier works. In the end, I was able to reflect a significant portion of the ideas and concepts in these excluded works by including articles of that type in one of the three *Selected Papers* volumes.

SERIES EDITOR'S INTRODUCTION

The details of editing proved more complex. Much to my chagrin, I very humbly learned how much work goes into a project of this scale and complexity. We decided early on that the level of editing required to bring the prior publications up to the high standards of contemporary academic philosophical publishing would necessitate revised editions. We also decided that since we were preparing revised editions and Naess was alive and could review the work, we would make the role of the editor invisible and not include tedious footnotes chronicling all the changes, however significant they might be. The historical significance, intricacy, and sheer magnitude of *Interpretation and Preciseness* (SWAN I) warranted special consideration. For these reasons, we decided that it would be best to prepare only an edited version for this volume and not attempt a complete revision as with the other volumes. In the early stages of the project Naess and I worked together closely, intimately. In my effort to eliminate errors and to enhance readability, flow, and clarity of argument, I brought Naess question after tedious question when I first embarked on the project (particularly when I was in Norway as a Fulbright Scholar in 1996). After working through several manuscripts, Naess decided to place the remainder of the responsibility for revising and editing the manuscripts in my hands.

We have made our best effort to reconcile inconsistencies, make corrections, and chase down incomplete bibliographic references (in most cases no bibliographies existed for the original works). I regret, however, that some imperfections remain. I am also responsible for any new errors that have been introduced—their existence, unfortunately, is unavoidable. I am, however, heartened by a conversation I had with Naess midway through the project, after he had reviewed several drafts of revised manuscripts. He commented that at least 90 percent of my revisions resulted in improvement and that no significant misinterpretations had been introduced. Given the nature and complexity of this project, that sounded like odds I could live with.

Acknowledgments

A project of this magnitude, by its very nature, represents the labor and love of an entire community. It could never have gotten off the ground, much less been completed, without a fantastic and deeply committed team. I have been blessed by the opportunity to work with, learn from, and re-

SERIES EDITOR'S INTRODUCTION

ceive guidance and support from so many talented friends and colleagues. It's been a wild ride; I owe you all a tremendous debt of gratitude.

First, the inspiration for the *Selected Works* and the majority of its financial support are due to the foresight and generosity of "Miracle Doug," Douglas Tompkins, president of the Foundation for Deep Ecology (FDE). Thanks for your vision, Doug. Quincey Tompkins Imhoff, former executive director of the Foundation (and current vice president of the board), also deserves recognition for her tremendous support during the early years of the project, as do program directors Jerry Mander and John Davis. Special thanks also go to Sharon Donovan, the Foundation's publishing manager, who in the project's final years has guided it through a long and sometimes circuitous path to completion. The Foundation has also always had an amazingly gifted and dedicated staff. At one point or another, many of its staff had a hand in helping this project along—offering assistance at a key point, a kind word, inspiration, or simply good cheer and a smile. Thank you, Denise Wilson, Debi Barker, Esther Li, Lizzie Udwin, Julie Lindow, Miyo Sakashita, and Emily Lydgate.

I was also supported by the Fulbright Foundation with a senior research/teaching fellowship at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. Additional support came from Western Michigan University. Special thanks go to WMU's dean of the College of Arts and Sciences, Leonard Ginsberg, and to my chair, Thomas Bailey. My colleagues at Western Michigan University also deserve thanks for their tolerance and succor while I focused all my available energies on this project. I am grateful for their flexibility and generous support. Wil Emmert, one of WMU's Research and Program officers, also deserves a great thanks for his patience and skillful assistance.

The project has been blessed with a distinguished advisory board—Robert S. Cohen, Bill Devall, Alan Drengson, Ingemund Gullvåg (deceased), Per Ingvar Haukeland, Kit-Fai Naess, Nicolas Rescher, George Sessions, Michael Soulé, Douglas Tompkins, and Jon Wetleson. All of the advisers offered significant assistance in one form or another. Bob Cohen graciously shared his expertise and offered invaluable advice, encouragement, and support throughout the project. Bill Devall gave encouragement and helped bring volume X to completion by coauthoring its preface.

SERIES EDITOR'S INTRODUCTION

George Sessions offered advice on the selections for volume X, provided guidance, and carefully reviewed a draft of this introduction. His suggestions greatly improved its flow and clarity. Kit-Fai Naess's tremendous moral support and great assistance in locating obscure documents and preparing bibliographies were invaluable.

Alan Drengson's contribution as a project adviser and in the project's final year as Associate Editor deserves special mention. At a crucial time, when the project was stalled in its later stages, Alan stepped up to the plate and played a key role in helping shepherd the project to completion. In particular, he took over most of the day-to-day project-coordination responsibilities for the final year of the project. He reviewed the copyedited manuscripts for volumes I, VIII, IX, and X, oversaw preparation of the author's prefaces to each volume and the editors' prefaces to volumes VIII, IX, and X, and reviewed the final manuscript proofs. This was not an easy task. I owe Alan a great debt for his fortitude, commitment, and generosity. For his contribution to the difficult and taxing responsibility of overseeing the final preparation of volume I, he has been credited as its sole editor.

I am lucky to have been supported by two astonishingly capable, committed, and patient project assistants. Kim Zetter played a critical role in getting the project off the ground and keeping it on schedule for the first three years. Later, Barbara Pijan helped steer the project back on track and over some awkward obstacles after it had run off course. Their talent and dedication played a major role in bringing to life the books before you. Thank you, Kim and Barbara, for your stalwart devotion to the project.

The beautiful and elegant design of the series is the work of Tomatsu Yagi and his nephew Akira Yagi. Ralph Fowler played a significant role in executing the Yagis' design and by filling in any missing gaps. Ralph also performed the typesetting for volumes II–VII. The skillful and efficient crew at BookMatters performed the remainder of the typesetting. Katherine Silver handled the Brobdingnagian task of project management on volumes I and VIII–X and the last crucial stages of the project with aplomb, attention to detail, and fortitude.

The bulk of the project's copyediting was performed by the meticulous and supertalented Anne C. Collins, Ph.D., copyeditor extraordinaire. Additional copyediting was provided by Mary Anne Stewart and Kathy Walker. Indexing was performed by the immensely competent Nancy Mul-

SERIES EDITOR'S INTRODUCTION

vaney of Bayside Indexing Service, Julie Shawvan, and Leonard S. Rosenbaum. Proofreading was provided by Carrie Pickett.

Ingemund Gullvåg translated *Which World Is the Real One?* Iver Ørstavik provided the translation of "Experts' views on the inherent value of nature." The original editions of Naess's texts were keyed or scanned by the able and efficient crew at AgAccess—David Katz, Karen van Eppen, Jacob Katz, Rachna Boon, and Tim Rice. Additional keying of articles for the *Selected Papers* volumes was provided by Nancy Ropecka and Jane Drengson. Barbara Pijan, d Jones, Tony Hainault, and Debbie Reid deserve thanks for their careful and thorough transcribing of more than thirty-five hours of discussions with Arne Naess. Thanks are also owed to Tim Quick for his help with bibliographic research for volumes I and VIII–X, and to Kelly McKernan for assisting Alan with photocopying and faxing. In addition, a special thanks goes to Robert P. Goldman, Sarah Kailath Professor of Sanskrit and Indian Studies at the University of California Berkeley, for generously and graciously offering assistance on contemporary Sanskrit and Hindi terms.

I am grateful to the dedicated and very patient staff at Kluwer Academic Publishing. I am sad that our original editor, the immensely talented Annie Kuipers, who first recognized the importance of this project, did not live to see it come to print. Stephanie Harmon, Annie's replacement, worked closely with me on editorial matters and on finding high-quality recycled paper, cloth, foil, and other materials that meet the strict environmental considerations of FDE. In the final five years, the able and gifted Charles Erkelens was our editor.

Additional advice and moral support were provided by colleagues, friends, and family: Aimee Carroll, Kirsten Coyne, Paul Craig, Neal Goodwin, Byron Hahn, Ladislav Hanka, Alastair Hannay, Anna Leidberg-Miron, Danny Moses, Richard Norgaard, Max Oelschlaeger, Brian Recht, Stephanie Sarvar, Ed Saxon, Geir Michael Sommerhein, Petter Sorum, and Kristin Walstad. Thanks for your efforts to coax me out of the cave.

Special thanks go to d and Reuben for their forbearance and succor. Someday, all too soon, Reuben will recognize that the invisible "work fairies" that were constantly pulling me back to my office don't actually exist. I can't wait.

Most of all, thanks to Arne Naess for placing his trust in me—it's been

SERIES EDITOR'S INTRODUCTION

a gift, something like an extended trudge up to Tvergastein, but without the fresh air and perspective. Taking on this project has been somewhat like receiving Pandora's box as a present—all sorts of ills and plagues reared their heads along the way. I often felt that I was on a never-ending climbing descent in the night. I was always wondering about rappelling off my rope into the abyss.

The SWAN has taken flight, and I have landed on firm ground—I think? In all seriousness, I learned invaluable lessons. The more I worked through Arne's writings, the more open-minded and optimistic I became. I found myself cultivating perspective and looking at the problems and challenges before me with fresh insights. I also found myself responding with more grace and equanimity in my efforts to counteract the numbing effects of contemporary society.

It is strange and ironic, however, that in being the series editor for the *Selected Works* of the father of deep ecology I spent so much time inside, chained to a desk. But this is part of the paradox of working with Arne Naess. I am reminded of one of my favorite poems—Gary Snyder's "Axe Handles." The last few lines read:

Pound was an Axe,
Chen was an axe, I am an axe,
And my son a handle, soon
To be shaping again, model
And tool, craft of culture,
How we go on.

And then it makes sense.

Harold Glasser
2004

Notes

1. In writing this essay, I found myself drawing on more than twelve years of friendship with Arne Naess. A simple bibliography could not do justice to describing how this subtle and multilayered gestalt has been formed. My perception of Naess and his work has been shaped by more than thirty-five

SERIES EDITOR'S INTRODUCTION

hours of transcribed conversations between us, countless other conversations, letters, scraps of paper, e-mails, and Arne's copious annotations in my own books and articles. Camping trips, bouldering, hikes, and cross-country skis have also helped inform my understanding of Arne Naess the fiercely competitive, playful, elfin trickster, who springs to life in nature. I have benefited from three extended visits to Norway, including a Senior Fulbright at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. I have also spent other stimulating periods of time with Arne in Svalbaard, England, California, and the deserts of Arizona and Nevada. Finally, and probably most important, I have been inspired and forever changed by my own reading and editing of his work. In this regard, both previously published and unpublished materials have been influential in forming my own perspective on Arne Naess the philosopher. One key published source has been Naess's "How my philosophy seemed to develop," in *Philosophers on Their Own Work*, edited by Andre Mercier and Maja Svilar (Bern: Peter Lang, 1983), pp. 209–26 (in SWAN IX). Another source for insightful material on Naess and A. J. Ayer (as well as six of their contemporaries) is a book created from debates by philosophers for Dutch National Television. See, especially, "The glass is on the table: An empiricist versus a total view," in *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), pp. 11–68 (in SWAN VIII). Finally, additional perspective was offered by an article that discusses Norwegian philosophy from the end of the Second World War to just before 1980: Arne Naess and Jon Hellesnes, "Norway," in *Handbook of World Philosophy Since 1945*, edited by John Burr (Westport, CT: Greenwood Press, 1980), pp. 159–71.

On some of the fine points of this essay, I have benefited from extended conversations with my colleague and old friend George Sessions. I have also profited, over the years, from the significant literature that has been created to shed light on Arne's life and work. Many of the ideas and thoughts introduced in this essay—drawn from my own firsthand experiences with Arne—can also be found in these sources. In many cases, issues only touched on here are taken up in much more detail in those sources. Five key references for historical material on Naess and the evolution of his philosophical approach are identified below (two of which are videos). A wealth of additional material is available in the five festschrifts for Naess (see details in note 15 below). The first of the festschrifts, *In Sceptical Wonder: Inquiries into the Philosophy of Arne Naess on the Occasion of His Seventieth Birthday*, edited by Ingemund Gullvåg and Jon Wetlesen (Oslo: Universitetsforlaget, 1982), contains the most thoroughgoing analyses and critiques of Naess's earlier philosophy that I am aware of, and many of the articles have insightful responses by Naess.

Singh, ed., *Environmental Ethics and the Power of Place: Festschrift to Arne Naess* (Varanasi, India: National Geographical Journal of India, 1994); Nina Witoszek and Andrew Brennan, eds., *Philosophical Dialogues: Arne Naess and the Progress of Ecophilosophy* (Oslo: Centre for Development and the Environment, 1997; Lanham, MD: Roman and Littlefield, 1998); Andrew Light and David Rothenberg, eds., *Arne Naess's Environmental Thought*, special edition of *Inquiry* 39 (June 1996).
16. Arne Naess, *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre*, translated by Alastair Hannay (Chicago: University of Chicago Press, 1968). In the 1970s, philosophy was still influenced by the events of the Second World War. Heidegger's flirtation with National Socialism and the Hitler regime, and his unusual way of expressing himself, made it difficult for him to be considered a great philosopher. Naess's book on four contemporary philosophers was seen as unique because he interpreted in a scholarly and positive way both Heidegger and the fiercely anti-Heideggerian philosopher

SERIES EDITOR'S INTRODUCTION

Rudolph Carnap, a logical empiricist. Carnap, who was forced to flee Nazi Germany, could not fathom how Naess, as an old friend, could present positive discussions of Heidegger and himself in the same book. The other two philosophers included in the book, Wittgenstein and Sartre, also held completely incompatible views of philosophy, but Naess accorded them equally high positive appreciation.

17. For example, works by Naess that are still in print, such as *Ecology, Community, and Lifestyle: Outline of an Ecosophy*, translated and edited by David Rothenberg (Cambridge: The University Press, 1989), and *Life's Philosophy* (2002; see note 2), were not included, for obvious reasons.
18. In "How my philosophy seemed to develop," p. 215, Naess mentions the particularly strong impression, the magnificent expansion of his own "life's frame of reference," made by H. G. Wells's early popularization of the history of life, *Outline of History* (New York: Macmillan, 1920).
19. For detailed discussions of Naess's assessment of logical empiricism, see Arne Naess, "How can the empirical movement be promoted today? A discussion of the empiricism of Otto Neurath and Rudolph Carnap," in *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. Vandormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), pp. 107–55 (in SWAN VIII). (The original German version of Naess's article, "Wie Fördert Man Heute die Empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolph Carnap," was written during 1937–39.) For Naess's experiences attending the Schlick seminar, see Arne Naess, "Logical empiricism and the uniqueness of the Schlick seminar: A personal experience with consequences," in *Scientific Philosophy*, edited by Friedrich Stadler (Dordrecht: Kluwer Academic, 1993), pp. 11–25 (in SWAN VIII).
20. Naess, "How my philosophy seemed to develop," p. 222.

Schilpp (Chicago: Northwestern University Press, 1939), p. 597, as quoted in Wallace I. Matson, *A New History of Philosophy*, vol. 2 (San Diego: Harcourt Brace Jovanovich, 1987), p. 454.
23. Naess, "How my philosophy seemed to develop," p. 223. For more details, see Richard McKeon and Stein Rokkan, eds., *Democracy in a World of Tensions* (Chicago: University of Chicago Press, 1951). Naess, as the scientific leader of the project, was viewed as a UNESCO administrator; he was only credited as being the author of the questionnaire itself and the summary paper, although he was intimately involved with the project at all levels.

SERIES EDITOR'S INTRODUCTION

24. Naess went on to perform a reconnaissance of Tirich Mir (25,263 feet) in the Hindu Kush in the summer of 1949. He then led the successful Norwegian first-ascent team in 1950. The expedition, which included botanical and geological assessments of the region, is chronicled by the team members in Naess et al., *Tirich Mir: The Norwegian Himalaya Expedition*, translated by Sölvi and Richard Bateson (London: Hodder and Stoughton, 1952). Naess successfully pursued a second, vastly more technical expedition to Tirich Mir in 1964. His "The south wall of Tirich Mir East," *Himalayan Journal* 26 (1965): 97–106, discusses this expedition and includes interesting commentary on expedition philosophy and climbing ethics. The article appears in SWAN X, along with other papers on Naess's relationship to mountains and views on mountaineering.

"Ecosophy T" (a particular deep ecological total view), see Harold Glasser, "Deep ecology," in *International Encyclopedia of Social and Behavioral Sciences*, edited by Neil J. Smelser and Paul B. Bates (Oxford: Pergamon, 2001), pp. 4041–45. For a detailed discussion of deep ecology as an ecophilosophical approach with special attention to its policy implications and a discussion of deep ecology's relationship to Naess's earlier philosophical work, see Harold Glasser, "Naess's deep ecology approach and environmental policy," *Inquiry* 39 (1996): 157–87 (reprinted in Witoszek and Brennan's *Philosophical Dialogues*).

31. For anthologies on the deep ecology movement, which include articles by Naess and other deep ecology supporters, see George Sessions, ed., *Deep Ecology for the Twenty-First Century* (Boston: Shambhala, 1995), and Alan Drengson and Yuichi Inoue, eds., *The Deep Ecology Movement: An Introductory Anthology* (Berkeley, CA: North Atlantic Books, 1995).
32. Naess rarely responds directly and definitively to these criticisms—this is not his nature. Siri Naess, however, made an interesting effort to explore the potential of using Naess's Ecosophy T as an inspiration for a feminist normative system in her "Self-realization," in *In Sceptical Wonder*, pp. 270–81. She concluded that while Ecosophy T and her System F have much in common, Ecosophy T goes further by extending to all living beings its concern for activeness and creativity in relation to problems, egalitarianism, and support of the suppressed and exploited.

Author's Introduction to the Series

At ninety-two it is a great honor to be still alive and to witness the publication of my selected works in English. Few philosophers have their work published in a series, fewer still receive this honor before they die. When I was originally approached with the idea of publishing my complete works, I was overwhelmed and overjoyed, but added that not all my books and articles were important enough to merit such an honor. Selected works? Yes, and I am extremely grateful for this initiative and the final result, which presents a representative selection of my work from the earliest to the most recent. [*The Selected Works of Arne Naess* are hereafter referred to as SWAN.]

My interest in philosophy began with Spinoza's *Ethics*, which as a seventeen-year-old I was fortunate to read in Latin. I appreciated Spinoza's grand vision and trusted him implicitly as a person. I accepted that human beings could, and should, have a general outlook with the grandeur of Spinoza's, but I recognized that our individual views on this grand scale will not be identical. Through the years I have realized that there is a splendid variety of interpretations of Spinoza (SWAN VI and IX). His texts are exceptionally rich. As the years have gone on, I have focused on how he leads us to realize we can increase our freedom and sense of connection with the world through strengthening and intensifying our *positive* emotions. For example, loving and caring for our place and others leads to an expansive sense of being part of a much larger world. Emphasizing hatred and anger, on the other hand, makes us feel smaller and isolated from the world. Spinoza, as I interpret him, would express this by saying that "We are as large as our love." Increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow.

Before I left gymnasium [the end of secondary education] the headmaster asked me, "What do you intend to be?" My immediate answer was

AUTHOR'S INTRODUCTION TO THE SERIES

"A philosopher." In fact, I had already conceived of myself as one. I viewed the writings of many contemporary philosophers that I was familiar with, however, as vague and airy and certainly not as inspiring as Spinoza.

My doctoral thesis in philosophy of science was an effort to remind us that in science the content of a theory is not independent of research behavior—the activities of observing, confirming, disconfirming, and so on, and that these are set within a deep context of place, history, and culture. Later, as a postdoctoral researcher at the University of California at Berkeley, I studied the behavior of experimental psychologists doing animal research.

In 1934 and 1935 I studied in Vienna and while there became a member of the famous Schlick seminar, the main discussion group of the Vienna Circle. Their quest for clarity and cordial cooperation in pursuit of knowledge led me to appreciate that "What do I mean?" is an open question. I concluded that we never intend to express anything extremely definite, even in mathematics or symbolic logic. I saw the importance of using empirical methods to find out how we actually use certain expressions and sentences. I developed and applied a wide variety of such methods, which became part of the core for the empirical semantics that runs through my work. I continued to do this type of research into the 1990s, my last project being one in which I questioned experts and policy makers about their ideas of values intrinsic to the natural world (in SWAN X).

In one of my earlier studies, I reviewed about 700 articles from philosophers concerning their use of the word *truth*. For the most part, I found these unconvincing and soon started on empirical studies of the use of *truth* among ordinary nonprofessional people and schoolchildren (in SWAN VIII). Many philosophers seemed to assume that ordinary people hold very naive views about these deep matters. I found through research that, on the contrary, the views articulated by these "ordinary" people were every bit as sophisticated as those held by professional philosophers. This reinforced my conviction that, generally, we greatly underestimate ourselves. Much academic philosophy was narrowly focused and abstract. Philosophers who elicited interest in wide-ranging issues of practical and global importance, such as nonviolence and social justice, have in my lifetime said things that were considered creative, but often too far out. In spite of consistent proclamations that science neither would nor could take over all the problems

AUTHOR'S INTRODUCTION TO THE SERIES

discussed by philosophers, I tried to argue in ways that reminded readers of science done as open inquiry, and I tried to emphasize that it is occasionally necessary to perform empirical research to illuminate or support a philosophical viewpoint.

My empirical and historical research led me to realize that there are no certainties and that there is a great diversity in our spontaneous experience as well as endless ways to describe and appreciate the complexities and values of the world. Thus, I realized that I am one of those lifetime seekers that the ancient Greeks called a *zetetic* (see SWAN II and VIII). From my research on scepticism and the foundations of science and logic, it became clear to me that pluralism (every event has many descriptions and possible outcomes), possibilism (anything can happen), and a healthy scepticism (always seeking the truth but never claiming it) make up the most consistent approach to respecting the perspectives and experiences of others, human and nonhuman.

From my empirical studies of semantics, and from my knowledge of several languages, I came to appreciate the complexity of communication. Being committed to Gandhian nonviolent communication, I saw the importance of avoiding dogmatism and fanaticism. One of the most important discoveries coming from this research, leading to the publication of my major book, *Interpretation and Preciseness* (SWAN I), was the insight that we cannot avoid values in any field of endeavor or research. There are no value-free inquiries or theories. Even if we refuse to express our values, this is itself an expression and choice of values. We must, therefore, be clear about our value choices and try to make them explicit. The choices we make, as Spinoza pointed out, shape the quality of our lives, and values emphasizing positive emotions or feelings are expansive and lead to our growth. We must become ever more aware of our choices and the values involved. Even pure logic assumes certain norms. Empirical research can shed light on these matters. My colleagues in philosophy often found my empirical work perplexing. I, in turn, grew to underrate the necessity of visiting great centers of philosophy, as I preferred to be close to or in the mountains.

When I visited the United States, it was mostly to climb in the mountains or walk and camp in the desert. On one fortunate visit, I dropped in at the graduate students' discussion room at Harvard. Speaking with students who were writing their doctoral theses in philosophy, I understood that my

AUTHOR'S INTRODUCTION TO THE SERIES

knowledge of contemporary philosophy, and of recent important contributions in its various fields, was narrowly limited to special themes of lively personal interest. Even in later years, the tendency to take personal inclination very seriously colored my contribution to the philosophical literature. As can be seen, though, from the titles in these *Selected Works*, my strongly felt interests span a rich variety of fields, philosophical traditions, and movements.

Since childhood I have experienced an intense joy in being together with animals and plants and in contemplating the immense evolutionary development of life on earth over millions of years. From an early age I also developed an intense love for mountains and for being in them. Much of my creative philosophical work was done at Tvergastein, my mountain hut in Norway (see SWAN X). My devotion to outdoor life is in the Norwegian tradition called *friluftsliv* (literally, free-air-life). In many respects, I approached philosophical and cross-cultural studies as if I were a field ecologist or naturalist. It was against this background that my work from the 1960s onward focused with close attention on cultural diversity, biodiversity, sustainability, and the deep ecology movement.

My work since the Second World War has been increasingly within movements such as those furthering social justice, peace, and ecological responsibility. During the war, I engaged in anti-Nazi activism, and from that time also in promilitant Gandhianism, a nonviolence that is not pacifist in the usual sense but insists that if it is a bloody fight for justice against injustice, we seek "the center of the conflict" and, if necessary, cooperate with people who use arms. During the Cold War, I participated in the "third side," against both communism and extreme anticommunism, for example, as the scientific leader of a UNESCO project bringing Marxist and anti-Marxist politicians and political science researchers together in an unbiased discussion of the essence of democracy and freedom. Some of the relevant publications are included in SWAN IX.

The broad spectrum of books and articles included in the *Selected Works* represents, in many ways, a chronicle of my passions and influences. The *Selected Works* record, albeit in an inevitably fragmentary way, one possible expression of these. My dream and hope is that some readers will be inspired by their sheer variety, and that young philosophers will be encouraged to let strong personal motivations steer their studies.

AUTHOR'S INTRODUCTION TO THE SERIES

Working habits vary. Some people write an article and go on to the next without looking back on the old one; others come back from time to time, radically revising and changing the old one. The latter is my way of working. Lecturing in many places about these subjects, I have found it natural to revise the old manuscripts until sometimes very little is left of the original. Therefore, I have always viewed my writing as preliminary; a year, five years, ten years after publication of the first editions I have itched to revise, *thoroughly* revise them. When my first book was printed in 1936, I went to watch the hulking presses printing out one page at a time. I was terrified, thinking of mistakes or some awkward sentences being duplicated again and again.

When I was offered the opportunity to have a selected-works series published, I immediately thought I would like to review all my work and ask how, from today's perspective, I might answer the difficult questions I had earlier attempted to probe. Such a task would have been a particularly difficult proposition, because although many of my books and articles contain new ideas, the ideas are often not developed as well as I might have hoped. But alas, I am saved—at my age there is not time for me to accomplish such a comprehensive reevaluation of my work; I do not even have the capacity to do it now in any case.

Who could contemplate undertaking a publishing project of such ambitious proportions? Douglas Tompkins, mountaineer, entrepreneur, protector of wilderness in Chile and Argentina, and creator of the Foundation for Deep Ecology, is such a person. "Miracle Doug," as I call him, likes the idea that the deep ecology slogans and the deep ecology approach were introduced by a philosopher. I am grateful to him for his firm conviction, inspiration, and great generosity. My gratitude, however, extends well beyond my thanks to Doug, to others who have supported and championed this project.

Quincey Imhoff, when executive director of the Foundation for Deep Ecology, supported SWAN with generous grants and other contributions. SWAN has also benefited from faithful assistance and cooperation in the preparation and editing of the manuscripts. The late Professor Ingemund Gullvåg prepared the initial translation of *Which World Is the Real One?* (SWAN III). Professor Alastair Hannay translated the first edition of *Communication and Argument* (SWAN VII) and offered invaluable suggestions for improving the readability of the first editions of *Scepticism* (SWAN II),

AUTHOR'S INTRODUCTION TO THE SERIES

The Pluralist and Possibilist Aspect of the Scientific Enterprise (SWAN IV), and *Gandhi and Group Conflict* (SWAN V).

Most of all, however, I am grateful to Harold Glasser, the series editor, and his assistant, Kim Zetter, who oversaw all aspects of the project from design to production. Glasser's unique combination of intellectual tenacity, attention to detail, mastery of my work, and cooperative spirit made him a natural to take on the monumental task of selecting and editing my works. Glasser not only labored to improve the English and clarity of each manuscript, but his keen ability to ferret out countless technical and pedagogical errors has resulted in substantial new editions of volumes II–VII that are both far more comprehensible and accessible than the originals. I thank him for his valiant work on this project, both during his stay in Norway as a visiting Fulbright professor, where we collaborated on a strategy for revising the previously existing material, and in the subsequent years it has taken to complete the project.

From the beginning of the SWAN Project in 1994, Alan Drengson has encouraged and helped to move this work forward in numerous ways. Especially in the last crucial stages of completing volumes I, VIII, IX, and X, his help and editorial oversight have been invaluable. Thanks for his devotion, good humor, and positive enthusiasm. Thanks to both Drengson and Tim Quick for their extensive bibliographic research. Thanks to Bill Devall for his support and encouragement and especially his help on the completion of volume X, *Deep Ecology of Wisdom*. Thanks to Anne Collins for her outstanding work as the copyeditor of the SWAN volumes. Thanks to George Sessions for his support and encouragement.

Last, but certainly not least, immeasurable thanks go to my wife, Kit-Fai Naess, who has worked beside me throughout the years to provide invaluable assistance, encouragement, and inspiration.

Arne Naess

2004

Preface

by Alan Drengson

The twenty-one papers gathered together in this volume have been organized under four broad section titles: (1) Empirical Semantics and ‘Truth,’ (2) Zeteticism, (3) Empiricism, Possibilism, and Pluralism, and (4) Metaphysics, Morals, and Gestalt Ontology. The narrative threads and themes running through these essays are woven together by Arne Naess’s active practice of open inquiry, an inquiry that can be both detailed and comprehensive and is motivated by his strong sense of wonder and his passion to know the world *in as many ways as possible*. It is not by chance that Naess describes in sympathetic terms the way of the zetetic, or lifelong seeker of knowledge, truth, and wisdom (see section 2). As such a seeker himself, he strives to know the world by actively engaging in many ways of observing, analyzing, experimenting, and searching. He regards his writings in much the same way, as works in progress.

Since life is a creative process, not a finished affair, there is wisdom in seeking through open-ended inquiry. From his in-depth study of scepticism, Naess came to appreciate especially the wisdom of a form of Pyrrhonian scepticism called *zeteticism* (chapter 10, “Pyrrhonism Revisited”). The zetetic seeks above all to know truth. Although the zetetic trusts that it is possible to attain truth and knowledge, he or she remains open and does not claim the truth (chapter 11, “Trust and Confidence in the Absence of Strict Knowledge and Truth”). The ancient zetetics, like their modern counterparts, realized that the world of experience is ever changing, that every event has many descriptions, that the world is full of surprises and incomprehensible mystery.

Early in life Naess was impressed by the unity and aliveness that he perceived in the natural world. His sense of wonder was kindled by the

many beings he encountered while playing as a child in the Oslo fjords and in the alpine meadows near Mount Halingskarvet (see SWAN X, chapter 33). In these natural settings he realized that his spontaneous experience had a unity and a sense of personal meaning connected with the natural world. The quality and complex nature of this unity were illuminated for Naess when at age seventeen he began his lifelong reading and rereading of Spinoza's *Ethics* in the original Latin. These childhood experiences and his passionate interests led him on to a lifetime of learning, research, and writing. He became a philosopher in the grand Spinozan way and also a lifelong alpine mountaineer (not just a specialist rock or ice climber). Spinoza is one of many philosophical summits he has climbed (see SWAN VI). Both of these quests—in nature and in philosophy—unite expansive perspectives with appreciation for details and how systems work within systems. In these quests Naess discovered that systems of thought, cultural systems, and ecological systems run in parallel paths but also form intersecting patterns. There are worlds within worlds, as noted in Buddhist philosophy (chapter 20, “Gestalt Thinking and Buddhism”).

Naess approaches research, learning, and philosophy much as a field naturalist studies the life-forms of the natural world. He seeks to understand concepts and words in their natural settings of language, tradition, and culture, just as he tries to see the creatures of the natural world in processes interrelated to smaller and larger ecosystems. The natural world can appear in our personal and cultural narrative traditions in many ways. For Naess, mountains are central to his way of life and personal mythology.

Influenced by Gandhi, Naess also seeks to know and communicate nonviolently. He believes research should be neither destructive nor elitist. The most comprehensive inquiry is open, philosophical, and global; and the questioner uses as many methods and conceptual forms of organization and order as are appropriate to a subject or problem. In texts, for example, words form sentences and sentences are ordered into paragraphs, which in turn make up chapters. Chapters are part of the whole text or novel; the book is part of a literary tradition. The patterns of order seen in wholes as *gestalts* are reflected at every level, from tiny to large. This is true also for the patterns of research that appreciate details in larger systems of meaning in texts and spoken conversations, from single words to sentences, to paragraphs, to a whole story, to a series of related stories, and so on to a mythol-

ogy. Each text or conversation forms a whole made up of many gestalts; and this corresponds as well to the way our experience is formed (chapter 19, “Creativity and Gestalt Thinking”). There are endless ways to organize each of these patterns and subjects.

Open inquiry entails investigating any subject or problem on every level and using many methods (chapter 14, “Logical Empiricism and the Uniqueness of the Schlick Seminar”). Open inquiry brings together our cognitive, emotional, sensual, spiritual, intuitive, and other capacities into a total view reflecting our sense of the whole of life. Naess’s philosophical and research endeavors can be traced to a life purpose that is practically oriented to helping himself and others to realize themselves. He wants each of us to become all that we can be. Because Naess lives by nonviolence, philosophy for him is an active *loving* search for wisdom amid comprehensive values within a great diversity of worldviews. He thinks we each act *as if* we had a total view of the world and our lives, *as if* we knew our ultimate values, and *as if* we knew the relations between our own life condition and the rest of the world. He believes that each of us knows more and is far more capable than we usually realize. Open inquiry is a way to pursue articulation of our total view and life philosophy since it intertwines our own views with other worldviews. Our attempts to articulate these views at a global level—using values that are comprehensive—lead us to ask questions such as, Why do I live the way I do? What are my priorities? What is the meaning of life? What do I most care about?

Each of us has a unique way of experiencing the world, of trying to characterize our experiences, and of expressing our total view through spoken or written language, music, dance, art, and myriad other means. Our most basic freedom is to choose how we will live and relate to others and the natural world. We must have values and we must also know something about the world. Science, even when a solitary undertaking, is one way to pursue knowledge by way of specialized, organized activities that involve others. There are many sciences and many other ways of knowing the world, but all these ways of knowing by means of specialized subjects and disciplines address only discrete aspects of our total spontaneous experience, which itself is inexhaustibly deep and rich. Through open inquiry, as a recursive process of reflective self-awareness, we eventually discover a great pluralism, even within a personal life in a specific cultural context.

When we try to identify ourselves and who we are, we find that our self-knowledge depends on our place and its local traditions; our family; and our personal experiences, culture, and language. In other words, each of us is uniquely embedded in a narrative community. (For broad narrative contexts, see SWAN I, *Interpretation and Preciseness*; for more specific issues, see chapters 1 and 5 in this volume, “Common Sense and Truth” and “The Empirical Semantics of Key Terms, Phrases, and Sentences.”) To know ourselves more fully, then, we must know ourselves in different settings, contexts, and experiences. Even then, none of these can fully define the whole reality of our spontaneous experience.

When we move to global perspectives, we encounter a great diversity of languages and cultures. Naess looks at these as if he were a cultural anthropologist from another solar system. He believes that individuals who are ordinary citizens, not experts or specialists (chapter 5), are a rich source for finding out about the nature of important concepts central to worldviews and values (see chapters 13 and 15, “The Glass Is on the Table” and “The Spirit of the Vienna Circle Devoted to Questions of *Lebens-* and *Weltauffassung*”). What are these semantic connections to the world? Our experience, we find from careful, self-aware examination, is organized by *gestalts*, patterns of meaning and intention inseparable from values and feelings, bound up with thoughts and language. Common sense, as a whole way of responding, seeks *truth* in practical, everyday terms: to know what is the case (chapter 1). The same is true for descriptions of what is *real*.

Reality is complex, deep, and multidimensional. It is possible for each of us to have a unique personal life philosophy and worldview within a great diversity of ecological systems and cultures. Even if worldviews conflict, there can still be understanding. Knowledge and truth, in Naess’s approach, are neither relative nor absolute. There is no single aspect of reality that is the only true or important one. Rather, there are many experienced realities, and all are part of larger and more inclusive *gestalts*. Reality is ever changing and inexhaustible, as our spontaneous experience shows.

Open inquiry into science and similar human enterprises leads us to an inescapable conclusion: there is no evidence-based proof that the future is determined or that probabilities are necessities (see SWAN IV). Scientific theory is just one of many ways of describing diverse aspects of the whole rich world. Naess affirms that possibilism (anything can happen) is liberat-

ing and in tune with open inquiry as a way of life. The future depends on our own actions. We can choose to live in harmony with others and with nature. The quality of our lives and experiences depends on our value choices. The more comprehensive our values and perspectives, the less fragmentary our total view. To be comprehensive and inclusive we must be nonviolent, however. When violent, we are exclusive and separate ourselves from others. Nonviolence is welcoming and inclusive. There are no value-free forms of experience, inquiry, or action (chapter 16, “Do We Know That Basic Norms Cannot Be True or False?”). Naess agrees with Spinoza that active emotions such as love and kindness increase our feelings of connection with the world and give us joy. Positive emotions allow an expansive sense of relationships and self; they enable us to be more effective and to have a higher quality of life.

Open inquiry does not end with specialized knowledge or specific truths about factual matters. It seeks to bring together or unite all ways of knowing and feeling. Thus, it gives us a life of reason that is integrated and whole, one that includes values and feelings as important components of a worldview (chapter 21, “Kierkegaard and the Values of Education”). Naess uses many forms of investigation and analysis—ranging from questionnaires and interviews (chapter 4) to observations, experiments, and textual analysis—to pursue questions such as, What is truth? What and how can we know? What are values? Can basic norms be said to be true? (chapter 16), What is the role of intensity of feeling in relation to moral life and suffering? (chapter 18), and What is the best education for a high quality of life?

One form of investigation he uses is based on empirical semantics, since our comprehension of the world is dependent on language. Empirical semantics takes a descriptive approach and uses a variety of methods to study how everyday language in a specific place is connected with the lives, experiences, and practices of the people of that place. In his studies Naess found that *truth* as explained by experts was more limited and less creative than as explained by ordinary people, who said everything the experts said and more (chapters 2 and 5, “Logical Equivalence, Intentional Isomorphism, and Synonymity” and “The Empirical Semantics of Key Terms, Phrases, and Sentences”). Naess sees no limit to our use of empirical methods, even when they are not equated with the specific epistemology of a

specialized branch of knowledge such as semantics, sociology, or psychology (chapter 12, “How Can the Empirical Movement Be Promoted Today?”). All researchers, even philosophers, should be willing to use empirical methods whenever those methods are appropriate.

Everyday language is the widest and deepest base for illuminating people’s whole life experience through narratives. How can we better communicate, and how does language function in different inquiries? Science and math are specialized, theoretical undertakings that use highly abstract language and concepts. These abstractions are not the concrete contents of the world and should not supplant the wholeness of our spontaneous experiences and ordinary ways of talking. All aspects of our lives and the world are open-ended, inviting creative and original responses from us. The ultimate aim of education is to help us become lifelong, self-actualizing learners and creative persons (chapter 21). As mature, self-realizing persons we are able to articulate our life philosophy. We come to realize, as Naess has, that we can lead a life of deepening quality and appreciation by enjoying the complexities and diversities in the world, including life-forms, cultures, and personal lifestyles unlike our own. Diversity and differences should not be seen as threatening. They should be welcomed. From wider perspectives we can see them with equanimity, as Spinoza observed.

Even the most narrowly framed technical questions, such as an investigation of how the word *or* functions, can be brought into a larger inquiry significant for daily life (chapter 3, “A Study of *Or*”). Just as we can place tiny organisms in their larger ecological settings, so it is with words in a language: we locate them through studying actual contexts of use connected with local and larger narrative traditions of meaning. At the highest level of global narrative ordering, we find mythopoetic themes with ultimate value and state-of-the-world premises that underpin religions, worldviews, and philosophies of life. The spirit of cooperative research and inquiry that characterized the Vienna Circle was the most important thing Naess learned from participating in those discussions (chapter 15). This for him is friendly, community-spirited inquiry that can investigate any subject, including worldviews. It opens to a way of life enriched by wonder as we find ever more perspectives, deeper feelings, greater clarity, and more unifying insights.

This volume focuses the spirit of open inquiry on values, knowledge,

PREFACE BY ALAN DRENGSON

and truth. In it Naess helps us better appreciate the complex structures that compose our whole unified spontaneous experience. We each can find ways to live a meaningful life within this highly pluralistic world, all the while expressing our uniqueness. At the same time, we can cooperate with others to preserve cultural and ecological diversity.

Author's Preface

Reflections on My Papers and the Selections in SWAN VIII–X

During my active life as a researcher and author, I have published far too much to be a polished writer. I have a long practice of working a set number of hours each day, and at ninety-two I have lived a long life. I hold to this even when I live in my mountain hut, Tvergastein. Over the years I have carried in many precious big reference books to put in its “library.” Writing philosophy in the hut, while looking over a vast mountain and alpine landscape, gave me a different feeling and perspective than when working in my office at the university or in my study at home. Each setting is very different and seems to bring out different aspects of the same subject and of myself. There are also the differences in dialect and local customs that fed my search for an ever more complete total view. To me this diversity is good to appreciate for its own sake. Writing, like teaching, is a way to find out things rather than just a dull report on the past. Writing philosophy for me is an ongoing project, a kind of meditation; in a sense, it is something that I must continue daily, because I continue to have more and more gestalts integrated into my total view with feelings of wholeness.

I never regarded the papers or even the books I wrote to be final drafts, but always works in progress, since my life, philosophy, and worldview are all in an ongoing process of change. Altogether, I have probably written thirty or so books published in various languages, and some in several languages. I have had many coauthoring adventures. There are manuscripts of books started but still in progress. I probably have some finished but unpublished book manuscripts. In the area of smaller-scale publications and writings, there are many kinds of pieces from very short to very long—for example, short reviews, long reviews, discussions, definitional pieces, long

AUTHOR'S PREFACE

single-subject essays, historically oriented papers, formal logic pieces, empirical studies, studies of conceptual systems—pieces on so many different subjects that I am somewhat embarrassed by my lack of attention to other things. I almost always write with passion but am not so keen to keep detailed records of my scholarly research, and at Tvergastein these resources are limited.

I have hundreds of manuscripts of articles, reviews, and other nonfiction pieces in my collection. The SWAN project has been a wonderful undertaking because it helped me to get my works organized to be more accessible to a larger audience. My dear wife, Kit-Fai, has been so good to my work that I can only describe her acts as beautiful. She, along with Harold Glasser, Alan Drengson, and others, plied me with endless questions about my works and individual pieces, for references, for greater clarity, for a better organization in time, and so on. The result is an assemblage of more than seven hundred published and unpublished papers.

We were choosing books to publish and papers for the anthologies of my selected works in English. We settled on seven books to be republished as the first seven volumes in the SWAN series. After some discussion with others, we decided to have three volumes of my papers for a total of ten volumes. We pondered what to include in the anthologies of papers and how to organize them. The result is a collection of writings that is a very deep and broad representation of the large number of papers of my work. The first two volumes are devoted to all the subjects I have worked on, from earliest to latest. These collections (SWAN VIII and IX) are organized in thematic sections somewhat chronologically. We decided to devote the third collection to my writings on deep ecology, because they are the most complete example of a total view that I have been able to offer.

Deep Ecology of Wisdom (SWAN X) is in many respects the most complete volume in the series in that it shows the total sweep of my work. It shows how my comparative and ecological inquiries brought together all my interests and studies. It was also a natural place for me to apply empirical semantics guided by a personal mythology, an undertaking that in the 1990s was offered in my book *Hallingskarvet: How to Have a Long Life with an Old Father*. The Tvergastein article in SWAN X (chapter 33) is an example of the philosophical, empirical, and semantic studies that were saturated with this place through time. SWAN X also includes a comprehensive bib-

AUTHOR'S PREFACE

liography of my works in English, which gives readers the most direct access to this whole body of work. Everything in my work is represented, from Spinoza's philosophy on emotions and Gandhian nonviolent communication, to essays on ontology and mountaineering. All of my work comes together in SWAN X. Readers will see the role of my desire to further nonviolent communication and my scepticism about there being only one worldview that is "true." These reflect my love of diversity.

I have mountain perspectives on worldviews. So many of them are beautiful and so suitable to their places! It is a wonder for me to behold this creative diversity. I found the same on the ground around my hut in the extreme mountain arctic conditions there. Even there, worlds within worlds! In that setting, life energies and mysteries are ever present. I came to approach all research from philosophy to ecology as if I were a field naturalist. This is reflected in my writings. Writing for me is a process of creation, discovery, and systematization; an art that helps me to assimilate and be whole with the more I see, as time goes on, from so many different perspectives. A synoptic view, almost holographic, emerged in my writings in many places. Traveling a lot added to learning these things.

Questions of meaning, preciseness, and interpretation are central to all that I do. We greatly underestimate ourselves in relation to our capacities, but we also greatly overestimate (violently at times) the seeming importance of disagreements over words that are frankly not very precise. The very effort to become more precise is itself an enlightening process that, once started, continues with a natural flow on its own. It is a settled practice that flows through my writing. Gandhian nonviolent communication also runs through my daily writings and practices; it is a second nature. My writings are active engagements, and for this reason I do not find them boring or painful. It is a joy to write about these many subjects that have engaged my passionate interest, especially in relation to the natural world.

Readers of these three volumes of selected papers who want to see my work in a more or less organic way that is roughly historical should read these papers in order, SWAN VIII through X. Those who want an overall look at my whole program of research, writing, and lifestyle should first read volume X. They could also read the last two chapters in SWAN IX, "How My Philosophy Seemed to Develop" and "Deep Ecology and Education: A Conversation with Arne Naess."

AUTHOR'S PREFACE

I have been reflecting on my writings and the way I approach and feel about this work. Let me say something about the different research hares I have chased and the lesser peaks and major mountains I have climbed in the process. I will do this by focusing on a recent ten-year period, from 1987 to 1997.

What has made me eager over the decades to continue writing articles in such great numbers? My spontaneous answer is that these are important questions not only for me but also for everything that it is worthwhile to sustain or develop further. By chance, this very sentence exemplifies a question of this kind: what is meant by “not only for me but . . .” and who is the “me” here? Among such questions there are some to which, as an optimist, I feel I can still contribute. These questions fall into two categories: those related to the ecological crisis and those philosophical questions far away from the ecological crisis. Writing for me is a series of adventures that are part of a larger mythopoetic nature narrative.

I thought that in recent decades the environmental crisis articles would make up the majority of my papers during this time, but to my astonishment that is not the case. For example, in the five years from 1991 to 1995, 61 percent of the articles published [by 1997] deal with general philosophical issues, and 68 percent of the unpublished ones are of that kind. Some of the articles are short, only five pages, which in part explains the large number of articles—78 published and 130 unpublished—during this time. I do very little to get my articles published.

One of the philosophical articles has the title “We need philosophies as life- and worldviews.” Many articles, some used in lectures in various parts of the world, deal with what I hope will characterize university philosophy in the twenty-first century: addressing central questions of what constitutes a meaningful life, diversity of cultures, and the nature of reality. Who are we, where are we, and what do we want most? The last question concerns value priorities. University philosophy, *not* the philosophy of “the man in the street” or of writers in general, has been centered on our talk itself, not on what we talk about. It is often talk about talk. The latest fad has been to stop talking about the variety of conceptions of the world in favor of talking about what are called social constructions, just to mention a focus different from life philosophy and worldviews. (Is nature a big *social* construction?) Clearly, as soon as we start *talking* about anything, for example,

about what is “talk,” what is “social,” and what is a “construction,” we are using a *social* creation, *intersubjective* talking. This does not undermine our excellent, direct relations to the matters we talk about and, I am glad to say, have different views about, some of which are quite personal and individual.

I will not bother to explain all the approaches I have taken within the philosophical sphere. I shall only offer some hints. In ethics I have taught, lectured, and written on the conception of being a “traitor,” a word applied to tens of thousands of Norwegians who in different ways were “on the wrong side” during the Nazi occupation of Norway by Germany. Many who did not deserve it were put in prison. Many believed that Hitler would win the war and that the continued independence and freedom of Norway depended on maintaining good relations with the occupying power.

Norway twice has said “No thank you!” to joining the Common Market, now called the European Union. I have written against joining on the basis of a philosophy that favors cultural differences. The EU is a big step in the direction of economic globalization, a formidable obstacle to cultural integrity and diversity. Some call this effort of mine “applied philosophy,” and I agree.

I have called a class of life- and worldviews *Spinozistic*, and my own view belongs to this class, but that does not *imply* accepting as true or valid any of Spinoza’s axioms and theorems. A long series of my articles deal with Spinoza, especially the central position of strong active emotions as a requirement for increasing our freedom and power, a rather un-Western view! I have explored and written about many Eastern philosophies, including Indian and Chinese. Some of my articles compare Spinoza’s views with Buddhist philosophies.

Gandhian studies continue with what I call the “principles of Gandhian communication,” a form of strict nonviolence. The role of the mass media in tough conflicts makes fairness of central importance. Treatment of an opponent as a fellow human being must be without blemish, even when his views seem to be, or are, horrible, despicable, and idiotic—and even if he is a mass murderer. This treatment is *compatible* with the expression of a strong and honest rejection of the views and actions of an opponent.

Felt suffering has been an important theme in my papers for many years. There is a strange, socially and politically important underestimation of acutely felt suffering and an overestimation of a quantified but not necessar-

AUTHOR'S PREFACE

ily *felt* suffering. If by chance a hundred people living distant from one another simultaneously suffer from a slight headache, this multiplicity of persons does not make the felt suffering stronger. I am deeply interested in the quality, the *feelings* of strong suffering, not some “abstract sum” of suffering.

Suppose we have a chance either to rescue a person from continued, systematic torture or to diminish the slight pain of a million people. As I see it, the choice is ethically unproblematic: rescue the tortured person! Politically, the implication is clear: much greater effort is needed to help people in certain extreme conditions. This, of course, cannot be done without angering dictators. What I call the *intensity principle* in dealing with suffering is generally not considered valid, and the possibility of saving people from continued torture is judged to be very small. As I see it, the problem is that usually only conventional means are considered. We need people with imagination, people like those who rescued thousands of tortured persons during the Second World War and the occupation.

As a philosopher influenced by analytic philosophy and an admirer of mathematical physics, cosmology, and pure mathematics, I regarded the one-hundredth jubilee (1991) of the birth of Rudolf Carnap and Hans Reichenbach as an opportunity to rethink my opposition to their philosophical standpoints and to logical positivism in general. I deeply respect their work, and especially their clearness in the matter of premise-conclusion relations. I have worked hard with a normative system that has only one ultimate normative premise, “Self-realization!” It is a result of the influence of my studies in logic and formal systems. In their work, the logical positivists encouraged each other, discussed with fairness, and used each other’s insights. They were not afraid of real disagreements. This is very unusual in intense philosophical discussions! I try to be fair and cooperate in discussions with my critics in social ecology and ecofeminism.

Going back to the five years from 1986 to 1990, I see that my papers are colored by contributions to the deep ecology movement. There is, however, a notable exception in my writings: what I call *gestalt ontology*. Ontology is an old branch of philosophy that tries to characterize what is real compared to what only appears to be real. Might a birch be bright green and joyful, or is it *really* colorless? Is joyfulness perhaps only a “projection” of joy being felt by an observer? Very roughly, my answer is that *spontaneous experiences* are direct experiences of something real. Joyfulness is

on a par with tallness and specific weight, when we only talk about pure realness. The experiences have a gestalt character. They are complex wholes, not merely atomistic.

The focus on spontaneous experience may be of positive value for deepening and intensifying positive experiences in nature. This focus also accepts the status of negative experiences. If, for example, a city dweller exclaims "Horrible, threatening" when suddenly facing a large waterfall, it is inappropriate to counter with the assertion "You are mistaken. It is really beautiful!" As to the character of being threatening, one might say that it would be a mistake to predict that the water will engulf us. This is just what gestalt ontology says. We can even have a slightly different version; it leads into rather professional philosophical terminologies. Its main thrust radically undermines the claim that only the exact physical sciences show us what is real. On the contrary, they increasingly focus on extremely *abstract structures* of what is real and do not, as sciences, describe any *concrete contents*.

As an outline of my work (from 1987 to 1997), the above gives a rough picture that is a fair description for earlier periods. I should perhaps add a word about my only published book in the 1990s: *Hallingskarvet: How to Have a Long Life with an Old Father* (1995). The main title is the name of a great Norwegian mountain; the subtitle refers to my personal relationship with the mountain. Already at age ten, I looked upon this mountain as being like a wise, benevolent father, but also as a supreme place to live. (My own father died when I was about a year old.) I found in this place an outline of my *mythopoetic life vision*. Many others, I suspect, are today creating such valuable myths of their own. I hope my writings encourage them. If so, these works will serve a useful purpose. So, finally, I am at the end of this written narrative. I invite readers to find their personal paths through this varied and multidimensional terrain of my writings. Follow your own wild passionate feelings.

2004

A Necessary Component of Logic: Empirical Argumentation Analysis

Logic Has Empirical Components and Needs Empirical Research

The use in argumentation of the calculus of propositions, or of Alfred Tarski's theory of truth, or of any other formal logical instrument involving the terms *true* and *false*, presupposes some sort of agreement or similarity between formal usage and common usage. This relation is an empirical relation not adequately revealed through intuition, but capable of being increasingly clarified through painstaking research, applying some of the research instruments of contemporary social science.

What holds good of formal theories involving "true" and "false" holds good of the logical constants and the primitive terms of the so-called philosophical logics. In this paper I shall not elaborate on the use of terms but attack a broader subject, that of empirical components in argumentation analysis. In my view there is a startling difference in quality between the treatment of the formal and the empirical components of problems raised.¹

Empirical questions are largely "solved" through appeal to intuitions of a low degree of testability. The terms *true* and *false* are used in argumentation, and one may try to single out their various usages by means of empirical research. In one analysis, I did not succeed in reducing the usages to less than thirteen different kinds.

This article was reprinted with permission from *Argumentation: Approaches to Theory Formation*, edited by E. M. Barth and J. L. Martens (Amsterdam / Philadelphia: John Benjamins Publishing Co., 1982), 9–22.

In what follows I shall mention some useful conceptualizations in argumentation research.

Argumentation Analysis

The term *argumentation analysis* may cover a large variety of approaches, but I shall confine myself to one kind of approach among the many. It is characterized primarily by a painstaking way of treating certain empirical questions that arise when one studies cases of explicit argumentation. Cases of explicit argumentation usually occur as parts of discussions and debates, sometimes of a rather polemical kind. To deal with these empirical questions scientifically, we use history, psychology, sociology, political science, and so on, as auxiliary disciplines, as well as common sense and what we experience in daily life. In empirical argumentation analysis, cases of argumentation are studied as acts or processes of communication between people and carefully recorded in observational journals. (Today's televised debates furnish rich intersubjective material.)

The approach to argumentation analysis that I shall talk about here specializes in investigating the superbly *open and deep* kind of argumentation. It should, in my opinion, characterize philosophical research. In philosophy, the chain of arguments is never cut off for good where it is traditionally cut off, be it because nobody so far has asked further questions or because practical people or scientists say it is pointless to continue. I am thinking here of chains, for example, of the following kind: "Why do you hold that *p*?" — "Because *q*"; "Why do you hold that *q*?" — "Because *r*." . . . The "deep and open" approach to argumentation legitimizes continuation of the chain as long as the questioner can clarify what it is that he asks us to answer. This characteristic sets the approach apart from psychological and sociological studies of communication, and also from most classical and modern studies of rhetoric and debate. Increased collaboration with other approaches is not only possible, however, but highly desirable.

The approach is different from, but of course not incompatible with, those largely inspired by formal logic, such as that of Paul Lorenzen. An example of an argumentation rule in his approach is: if a person says *p* & *q*, it is sufficient to refute *p* or *q* in order to refute him, but if he says *p* v *q*, one then has to refute *both* *p* and *q*. Empirical studies do not start with propositions,

but with *utterances in concrete situations*. The functions of the utterances are normally complex, having relevant performative aspects, but careful analysis may result in “distilling” *p*’s and *q*’s appropriate for formal treatment.

A pronounced empirical approach such as the one I am advocating does not exclude theory construction. Botany is empirical, yet it contains, and also presupposes, theory construction. Debates, perhaps even more than flowers, inspire deep reflection!

Options in a Clarification and Assessment Game

One way of describing rules in use in a discussion (here between two persons, *A* and *B*) that are intended *to clarify and to assess* arguments in terms of options, is as follows. (*T* and *U* stand for utterances in the form of declarative sentences.)

(1) *A*: *T*.

(2) *B*: (2.a): Yes. (2.b): No.

(2.c): Please be more precise!

(2.d): Please be more understandable but within the framework of preciseness relations!

(2.e): Announce kind of claim. Three options: the sentence was meant

1. not entirely as a clarification assessment (but, for example, as a somewhat performatory, persuasive, rhetorical, exclamatory, hortatory . . . remark); or
2. as a theory formulation; or as a factual, descriptive, observationally true claim; or as a correctness claim; or as a theoretical acceptability claim; or . . . ; or
3. as a postulational contribution; as an invitation to accept a statement for the sake of the discussion.

(3) *A*: (3.a) as a reaction to (2.a): T_1 (a tentatively more precise formulation, put forward by *A* in order to test whether there is real agreement of some kind or other).

(3.b) as a reaction to (2.b):

1. pro-argument “ pro_1 ”; or
2. tentative reformulation: U , where $\text{Syn}(A, T, U)$ (that is, U is synonymous with T for A); or
3. tentative “precization”: T_1 .

(3.c) as a reaction to (2.c): T_1, \dots

From this kind of scheme it is clear that there are many options at each stage of a discussion. Furthermore, the number of “correct” or constructible courses of discussion increases very rapidly with the number of stages. As early as stage (3), the number of possible discussion situations is perhaps of the same order as it would be in a game of checkers.

In the next section, I shall concentrate on the move “Please be more precise!” either as a move made by the receiver or as a move by the speaker who makes his or her formulation more precise in order to test (that is, confirm or disconfirm) an argument for agreement or disagreement.

Analysis of Agreement and Pseudoagreement

Let us consider the following discussion, which is the shortest possible specimen of a class of very common discussions, to be called discussions of type D_1 (with A_1 and A_2 used as values for the participant variables A and B):

(1) A_1 : The newspaper is thin today.

(2.a) A_2 : Yes. (2.b) A_2 : No.

(3) A_1 : I mean, the newspaper has few pages today.

(4.a) A_2 : I agree. I thought you meant that the newspaper contained little news.

(4.b) A_2 : I disagree: the newspaper does *not* have few pages. I thought you meant that the newspaper contained little news.

Let me introduce three abbreviations:

T_0 : The newspaper is thin today.

T_1 : The newspaper has few pages today.

T_2 : The newspaper contains little news today.

With “syn” standing for “is synonymous to” and $-T$ standing for the negation of T , the above discussion may be rendered as follows:

Discussion, type D_1 :

- (1) $A_1: T_0$
- (2.a) $A_2: T_0$
- (2.b) $A_2: -T_0$
- (3) $A_1: T_0 \text{ syn } T_1$
- (4.a) $A_2: T_1, T_0 \text{ syn } T_2$
- (4.b) $A_2: -T_1, T_0 \text{ syn } T_2$

A person A_1 sends the declarative sentence T_0 to another person, the receiver A_2 . A_2 sends back his utterance of agreement or disagreement with T_0 . Concerning the verbal usages of A_1 and A_2 , we know that for A_1 , T_0 is synonymous with T_1 but not with T_2 , and for A_2 , T_0 is synonymous with T_2 but not with T_1 . It is reasonable to assume that, for each of them, T_1 and T_2 are more precise than T_0 .

Figure 2 is to be read horizontally, starting at the top:

If A_1 takes T_1 to be true (which he, as the sender, does in any case), and A_2 takes T_1 and T_2 to be true, then there is verbal agreement at (2.a) and real agreement at (4.a). If A_2 takes T_1 to be true and T_2 to be false, then there is verbal disagreement at (2.b) and real agreement at (4.a). Furthermore, there is verbal pseudodisagreement at (2.b). If A_2 takes T_1 to be false and T_2 to be true, there is verbal agreement at (2.a) and real disagreement at (4.b). Furthermore, there is pseudoagreement at (2.a). If A_2 . . .

Suppose this type- D_1 discussion has ended at step (4.a). Conclusion: there is real agreement between A_1 and A_2 , *but only relative to step (4.a)*. Let us suppose the discussion starts again, A_1 repeating T_1 as a step (5) and A_2

EMPIRICAL SEMANTICS AND ‘TRUTH’

A_1	A_2		Agreement Relation:		
T_1	T_1	T_2	verbal?	real?	pseudo?
t	t	t	a	a	
t	t	f	d	a	d
t	f	t	a	d	a
t	f	f	d	d	

Figure 2. Key: t = true; f = false; a = agreement; d = disagreement.

repeating T_1 as a step (6.a). After these moves, A_1 reveals a little more about what he means by T_1 , and the discussion takes on the same color as before:

- (7) $A_1: T_1 \text{ syn } T_{11}$
(8.a) $A_2: T_{11}, T_1 \text{ syn } T_{12}$
(8.b) $A_2: -T_{11}, T_1 \text{ syn } T_{12}$

If this second installment of the discussion ends at step (8.b), then it ends with real disagreement in relation to (8.b) and with pseudoagreement in relation to steps (2.a) and (4.a). Consider the following example:

- (7) A_1 : I mean, the newspaper *available here* today has few pages.
(8.a) A_2 : I disagree. I thought you referred to the newspaper with today’s *date*. (I got my copy in the city. It really has few pages.)

The diagrammatical representation (figure 3) is similar to the foregoing one.

Discussions of type D_1 may continue indefinitely. As a consequence of the steps taken, agreements and disagreements will be realized, as follows:

- | | |
|--|--|
| At the end of step (4.a), we may conclude: | real agreement between A_1 and A_2 about T_0 . |
| At the end of step (8.b), we may conclude: | real disagreement about T_0 ; pseudo-agreement in relation to steps (2.a) and (4.a). |

A_1	A_2		Agreement Relation:		
T_1	T_{11}	T_{12}	verbal?	real?	pseudo?
t	t	t	a	a	
t	t	f	d	a	d
t	f	t	a	d	a
t	f	f	d	d	

Figure 3. Key: t = true; f = false; a = agreement; d = disagreement.

At the end of step (12.a), we may conclude:	real agreement about T_0 ; pseudo-disagreement in relation to step (8.b).
At the end of step (16.b), we may conclude:	real disagreement about T_0 ; pseudo-agreement in relation to step (12.a).
At the end of every step (4i.a), where $i=1,3,5, \dots$, we may conclude:	real agreement about T_0 .
At the end of every step (4j.b), where $j=2,4,6, \dots$, we may conclude:	real disagreement about T_0 .

From the above, we conclude that either “real agreement” is to be understood as “real agreement in relation to step x in an argumentation,” or else real agreement is something unverifiable. The “relational real agreements” confirm a hypothesis about agreement; the “relational real disagreements” disconfirm a hypothesis about agreement. That is, they yield confirming or disconfirming *instances* in relation to the working hypothesis. Analogously, *pseudoagreement* and *pseudodisagreement* are relational terms, too.

Insofar as agreement is taken to be agreement about truth or falsity, we may conclude: the attribution of truth or falsity to something said in a discussion is in principle always ad hoc, preliminary, and tentative. If A_2 answers “true” at steps (4.a) and (12.a) in our example, this does not preclude his saying “false” at (8.b) and (16.b). A vaguer, more general conclusion is that verbal agreements and disagreements always remain essentially verbal. Agreement about *propositions* is never *reached* through argumentation but remains a more or less well confirmed hypothesis.

Degree of Definiteness of Intention (Discrimination Acuity) as a Factor in Argumentation

The simplest way in which the finite degree of the speaker's definiteness of intention influences patterns of argumentation (for example, with the D_1 pattern) runs as follows: At stage (2), participant B asks A whether by expression T_0 he means (the same as by expression) T_1 or (expression) T_2 . At stage (3), A answers that he has not made, or that he does not make, this distinction. B then stops the D_1 -type discussion at stage (4), because if T_1 were meant his answer would be yes, whereas if T_2 were meant it would be no. B may take the initiative in a new discussion by asking how A would justify not making the distinction.

In our example of a D_1 discussion, A_2 may at step (4) say, "I did not think of the distinction between being physically thin and being journalistically thin!" A_2 's *degree of discrimination* stops short of a distinction between T_1 and T_2 . A_2 may admit the relevance and validity of this distinction, and may take a stand on it. In that case, the discussion may continue.

In many cases the instigator of a discussion *must* have thought about a certain distinction, we would say. Consider the following start of a discussion (not belonging to the class D_1):

- (1) *The General*: Our glorious attack on the enemy starts tomorrow at five o'clock.
- (2) *The Major*: Herr General, do you mean five o'clock in the morning or five o'clock in the evening?
- (3.a) *The General*: Alas, that distinction did not occur to me.

The general's answer is clearly relevant for the communication intended by him. In other cases, the relevance of a question can be disputed; in still other cases, a question is clearly irrelevant. Here is an example in which the relevance is disputable:

- (3.b) *The General*: Of course at five in the morning.
- (4.a) *The Major*: By "glorious," Herr General, do you mean . . . ?
- (5) *The General*: Irrelevant! (And irreverent?)

Here is a case of clear irrelevance:

(4.b) *The Major*: Taking note of Einstein's rejection of absolute time, may I ask the general whether by "five o'clock" he means . . . ?

(5) *The General*: Irrelevant!

The Hermeneutical Spiral as a Factor in Argumentation

Suppose at step (2) *B* expresses disagreement with *A*, and that *A* then continues the debate, offering a first *pro-argument*. It sometimes happens that, in the light of that pro-argument, *B* changes his *interpretation* of the initial formulation, T_0 , and now accepts it. The pro-argument then has a *retroactive effect*. Generally, every move of the participants may have retroactive effects.

Figure 4.

In discussions of great and complex systems of thought, retroactive effects are indispensable and decisive. An all-embracing system of thought tends to color everything (including the very principles of argumentation). Starting from the sentence of the system that is offered as number 1 (for example, in a book), there is no way yet of explaining it adequately to the outsider. By going back to it again and again, however, as one reads more of the text, one usually supposes that a (noncontinuous) development of understanding will take place, which eventually will furnish a kind of understanding of the system as a whole (including sentence number 1). To illustrate that movement, a spiral serves us better than a circle.

Suppose a person starts reading the first three sentences of a text, namely T , U , and V . He interprets them to mean T_1 , U_1 , V_1 and continues, now reading W . This makes him change his first interpretations of T , U , and V into T_2 , U_2 , V_2 (see figure 4).

The new interpretations T_2 , U_2 , V_2 furnish a new context for W . Rereading this sentence, he now interprets it as synonymous with W_1 . The next sentence, X , may in turn occasion changes of interpretation, and so on.

In the case illustrated, the reader of the text always has to go all the way back to the beginning of the text after reading a new sentence. In such a case, a spiral movement is created.

I apply these principles to a particular philosophy in "An application of empirical argumentation analysis in Spinoza's *Ethics*" (in SWAN IX).

A Study of *Or*

The “Natural History” of Logic

The development of logic as a scientific discipline has brought with it an immense, purely verbal, manipulatory system of discriminations. In the case of another science, that of mechanics, Ernst Mach long ago, in his *Die Entwicklung der Mechanik*, traced the development of concepts of force from crude commonsense notions to the pinnacle of abstract mathematical conceptualizations in modern science. Immense elaborations of the latter sort, and the lack of gross, overt, motoric reactions, have obscured the behavioral aspect of scientific concepts and have made it very difficult for the scientist to remember and recognize a connection with prescientific levels of thinking, perceiving, and acting. Many people regard it as something next to mysterious that formal logic, from a strictly causal point of view, has attained its present form. One of the great tasks of scientists trained both in logic and in the behavioral or psychosocial sciences is to make this development understandable. A “natural history” of logic must be written just as one might write the natural history of horses or of tulips. Studying the learning or understanding or use of an inference such as “if p or q , and not p , then q ,” we may, roughly speaking, proceed by mainly (nonverbal) behavioral and perceptual techniques or by mainly verbal techniques. The underlying assumption of the former is that basic logical distinctions and procedures have a behavioral or functional basis just as, let us say, distinctions in mechanics or morals do. We assume that we are always within the general system of human discriminations as studied by psychology or,

This article was reprinted with permission from *Synthese: An International Journal for Epistemology, Methodology, and Philosophy of Science* (Dordrecht, Netherlands: Kluwer Academic Publishers) 13 (1961): 49–60.

more generally, by the anthropological sciences—and this holds good whether the distinctions are made by schoolchildren or by eminent professional logicians. The professionals were once schoolchildren, and we assume there must be a process of learning or development that can be studied in detail from a causal point of view through all the stages of an individual's life.

Use of Logic and Talk About Logic: Meta-Logical and Object-Logical Verbalized Tasks

In using mainly verbal approaches, it is important to distinguish two subtypes that may respectively be called the meta-logical approach and the object-logical approach. Let us say that we are interested in the genesis of conceptions of 'or' as used in modern symbolic logic. Two main concepts are mentioned in modern textbooks, the exclusive and the inclusive 'or'. In elementary textbooks or in prepositional calculi, they are usually introduced by matrices:

Inclusive disjunction (<i>vel</i> -junction)		Exclusive disjunction (<i>aut</i> -junction)	
p	q	$p \vee q$	$p \wedge q$
T	T	T	F
T	F	T	T
F	T	T	T
F	F	F	F

Using questionnaires, we may, for example, ask boys and girls the following: "Peter made a bet that the Volga is in Russia or in Romania. It is in Russia as well as in Romania. Did Peter win the bet?"

Or we ask, "Do you use *or* in such a way that if Edward says that Peter or Paul is a bachelor and Peter is a bachelor, then Edward has told the truth?" Or, again, "Can one infer that Jack is married to Joan if one knows that he is not married to Phyllis and that he is married to Joan or Phyllis?"

In the last two cases, the attention of the subject is turned by the instructor toward rules of inference or concepts of 'or'. The subject is, so to speak, induced to take up the role of a logician, and not merely of somebody using logical distinctions. In these cases, he exemplifies opinions

about logical distinctions. His point of view is meta-logical. In the first case, the subject is likely to use a concept or notion of 'or' that he *has*, perhaps without knowing about it, and that he uses without being aware of using it. The questionnaire is object-logical rather than meta-logical. The distinction is closely related to that between *use* and *mention* in modern analytical philosophy.

Both approaches lean heavily on the verbal task instruction, the questionnaire. One may try to avoid this by experimenting on nonverbal behavior or perceptions.¹ One may ask, What do the conceptualizations connected with *or* consist of, and how do they show up in nonverbal behavior and perception? In the following, I shall not speak of this approach in which verbal stimulation and observation of verbal reactions are minimized. I shall concentrate on the verbal approaches. The main objective will be to show how the study of the ontogenetic development of logic presupposes studies of how people use certain terms. Without knowing how people use connectives, we cannot know their logic.

Or and the Sentential Connectives V and A of Symbolic Logic Systems

The following is a report of a study of inferences involving *or*. In logic, "*p* or *q*" is mostly said to be a disjunction or disjunctive connection between *p* and *q*. The term *disjunction* must in that case express rather different concepts, because *or* has many different functions. Two of the concepts have well-known names: "the inclusive or" and "the exclusive or."

Important logical operations involving disjunction can be easily exemplified within the thinking of fairly young children. Some subclasses or kinds of such operations may be symbolized by the following schemata:

1	2	3	4	
<i>p</i> or <i>q</i>	<i>p</i> or <i>q</i>	<i>p</i> or <i>q</i>	<i>p</i> or <i>q</i>	
<i>p</i>	$\sim p$	<i>p</i>	<i>p</i>	
$\sim q$	<i>q</i>	<i>p</i> and $\sim q$	<i>p</i> , and <i>q</i>	
			undetermined	
5	6	7	8	9
<i>p</i> and <i>q</i>	<i>p</i> and <i>q</i>	<i>p</i>	<i>p</i>	$\sim p$ and $\sim q$
<i>p</i> or <i>q</i>	not: <i>p</i> or <i>q</i>	<i>p</i> or <i>q</i>	not: <i>p</i> or <i>q</i>	not: <i>p</i> or <i>q</i>

EMPIRICAL SEMANTICS AND 'TRUTH'

If the symbols \vee and $\&$ are used for *or* and *and*, some of the schemata are transformed into valid (questionnaire responses invalid) kinds of inferences (within the system of certain contemporary logicians). For example, in the system PM, we have:

(1v)	(2v)	(3v)	(5v)
$p \vee q$	$p \vee q$	$p \vee q$	
p	$\sim p$	p	$p \& q$
$\sim q$	q	$p \& \sim q$	$p \vee q$
invalid	valid	invalid	valid

Similarly, writing a (abbreviation for *aut*) for *or*, we get in this notation:

(1a)	(2a)	(3a)	(5a)
$p a q$	$p a q$	$p a q$	
p	$\sim p$	p	$p \& q$
$\sim q$	q	$p \& \sim q$	$p a q$
valid	valid	valid	invalid

One may ask, What is the genesis of these inferences? Ontogenetically, we may ask at what stage, if at any, do people who are uninfluenced by professionals begin to infer in this way? Are they able to formulate the inference rules? Do they conceive the rules to be violable?

This approach started with or-clauses in everyday language and worked in the direction of symbolic logic systems. One may, on the other hand, work in the other direction: pick out valid inference schemata within the systems of certain logical textbooks and substitute *or* for \vee , and so on. Or, more generally, we desymbolize the texts. In that case we get inference schemata that to a definite person, P , may be classified into three types: valid, invalid, and nonsensical (awkward, puzzling). The following are examples of schemata that, for many people, fall into the third category:

(5)	(7)	(10)	(11)
$p \text{ and } q$	p	p	$p \text{ and } \sim p$
$p \text{ or } q$	$p \text{ or } q$	$q \text{ or } \sim q$	$p \text{ or } p$

If we work in this direction, that is, present the subjects with desymbolized propositions from formal logic, the question of how the subjects interpret the formulations is not pressing. The propositions to be presented might be picked out with this problem in view, and the phrasing of the

desymbolization carefully selected. However, when the point of departure is the inferences formulated by the subjects in their everyday language, the question of interpretation is far more difficult.

Many professional logicians today tend to state that in ordinary language *or* is used for the concept of exclusive disjunction. If this were true, we would have an important and easy way of studying inferences expressed by *or*. We would then know that if, for example, Betty says "Peter or Oscar lives in Paris," she has intended to use the concept of "exclusive or." If she then adds that "Peter lives in Rome, therefore Oscar lives in Paris," and we make some plausible assumptions, we shall then be able to conclude that Betty has made a valid inference of type (2a).

We would be able not only to say this, but also to say that Betty *intended* to make a valid inference of this kind and succeeded. Thus, we would be able to recognize certain inferences, some valid, some invalid, by pointing to the occurrence of *or*. Unhappily, there is evidence that this kind of simple observation is quite insufficient to establish such conclusions.

A Questionnaire Study of the Use of *Or*

To study inferences in which *or* is used to express a connection between propositions, I administered a set of questionnaires to about 350 American college students between the ages of seventeen and eighteen. They had never taken a course in logic.

Qs37 No. 13: Jack's Marriage

Text: Yesterday A and B made a bet. A said, "Jack is either married to Joan or he is married to Phyllis." B said, "I bet you five dollars this isn't so." A accepted the bet.

Questions:

1. If Jack is married to Joan, then would you consider that A won the bet?
2. If Jack is married to Phyllis, then would you consider that A won the bet?
3. If Jack is neither married to Joan nor Phyllis, then would you consider that A won the bet?
4. If Jack is married to both Joan and Phyllis, then would you consider that A won the bet?

A second questionnaire, Qs37 No. 15, is identical with the first except that *either* is left out. Lexicographers and other linguists generally suggest

that "either-or" stresses disjunction in various ways. One might therefore expect a stronger tendency among inferences expressed by "either-or" schemata to involve the concept of exclusive disjunction. The pairs of questionnaires gave evidence of this tendency.

A third questionnaire is closely related to the first two. The setting is more oriental, suggesting polygamy.

Qs37 No. 17: Abdullah's Marriage

Text: Half the male population of a Near Eastern country enjoy more than one wife. One day, *A* and *B* made a bet. *A* said, "Either Abdullah is married to Siri or he is married to Nina." *B* said, "I will bet you five American dollars that this isn't so." *A* accepted the bet.

Question: If Abdullah is married to Siri, but not to Nina, would you consider that *A* won the bet? (Four questions analogous to those of Qs37 No. 13 were asked. A representative of the Middle East objected that there is no country with such a high incidence of polygamy, and the questionnaire will not be used again.)

Through a pair of questionnaires, Qs37 Nos. 19 and 20, a use of *or* rather different from that in the previous texts was studied.

Qs37 No. 19: The Fellowship

Text: Yesterday *A* and *B* made a bet. *A* said, "Jack is qualified to receive a fellowship in this department." *B* said, "I bet you five dollars he isn't." *A* accepted the bet.

Fellowships in this department are open to those who are competent either in Greek or in Latin.

Question: If Jack is competent in Greek, but not in Latin, would you consider that *A* won the bet? (Etc.)

Qs37 No. 20 is identical to No. 19 except that *either* is left out. In order to be able to study the effect of changes in the relations between *p* and *q* on the tendency to make inferences such as "If *p* and *q*, then *p* or *q*," we used a questionnaire in which *p* and *q* had the same denotation, making "*p* and not *q*" and "not *p* and *q*" contradictory or awkward or absurd:

Qs37 No. 18: George Washington

Text: In history book *X*, one finds the statement "George Washington crossed the Delaware." In history book *Y*, one finds the statement "The father of our country crossed the Delaware."

A said to B, "Either X is right or Y is right." B said, "I will bet you five dollars that this isn't so." A accepted.

Question: If X was right and Y was wrong, would you consider that A won the bet? (Etc.)

Further, we used a pair of questionnaires such that "*p* and *q*" was made into a rather strange proposition:

Qs37 No. 14: *The Temperature*

Text: Yesterday A and B made a bet. A said, "This evening the temperature at the campus will be either more or less than 60° F." B said, "I bet you five dollars this will not be so." A accepted the bet.

Question: If the temperature at the campus turned out to be more than 60° F, would you consider that A won the bet? (Etc.)

In Qs37 No. 16, the term *either* is left out.

Being interested in a comparison between the American use of *or* (*either-or*) and the Norwegian use of *eller* (*enten-eller*), I translated questionnaires Qs37 Nos. 13, 15, and 17 and administered them to Norwegian students in their first year of college who were taking an introductory philosophy course. No. 13 with *either-or* and No. 15 with *or* included the story about Jack's marriage. No. 17 with *either-or* included the story about Abdullah's marriage. In addition, the Norwegian students were given a translation of the Abdullah questionnaire with *or* in place of *either-or*. Two Norwegian versions of the questionnaires were used, owing to some doubts concerning the most adequate translation. However, the differences in results were negligible, and the results will here be presented together.

Results

A survey of the results is given in table 1.

"Unclassifiabiles" are those answers to question 4 that were neither a definite yes nor a definite no; for example, "Yes, or perhaps no." "Unclassifiabiles" are also answers other than the standard yes, yes, and no to questions 1, 2, and 3, respectively; other answers were considered strong symptoms of misunderstanding.

One of the main results of our studies with Qs37 is that the conceptual structures involved in or-inferences at prescientific levels show marked

Table 1: Survey of Results of Or-Questionnaires Qs37.

o = question with “or”

N = number of subjects

variations depending on the subject matter of p and q and the verbal context (including the instruction).

At the one extreme we may place Qs37 No. 13, the story about Jack’s marriage in which *either-or* is used. About 90 percent (94 percent of the Norwegians) answered in a way that would be valid if their conceptual structure involved the exclusive disjunction. That is, their answers were of the FTTF variety. About 10 percent (6 percent of the Norwegians) gave answers suggesting TTTF.²

As for the interpretation of these 10 percent, it is tempting to say that they have drawn invalid inferences. For seventeen-year-old youngsters, the Qs37 questionnaires represent a very easy kind of task considered as a problem in reasoning. There is nothing positive to suggest that the 10 percent

did not *intend* to draw an inference in accordance with a rule “If p and q , then p or q .”

On the other hand, the answers of the 90 percent in no way prove the presence of a conceptual structure involving the rule of inference “If p and q , then not p or q .” We can only say that the answers are *compatible* with the hypothesis of the existence of such a rule or a disposition to follow such a rule.

We may place Qs37 Nos. 19 and 20 (the fellowship) at the other extreme. To these questionnaires, 98 percent answered as if they were thinking according to a rule of inference “If p and q , then p or q .”

The temperature questionnaire that used *or* gave results in between the previous ones, with 67 percent suggesting the use of an “exclusive or” inference.

A small team of graduate students of logic (and philosophy in general) was asked to try to construct a set of questionnaires of such a kind that the ratios between FTTF and TTTF answers would show a variation all the way from 9:1 to 1:9. They did not succeed, however, in finding suitable questionnaires for the ratios of the middle region, around 1:1; the nearest to this ratio was 2:1.

The task involves the use of hypotheses about what determines the answers of the subjects. Among the various hypotheses discussed, we may mention the following:

1. In betting contexts, subjects tend to use an inference rule corresponding to the “exclusive or” if they find the probability of p & q highly improbable. The marriage of Jack to both Joan and Phyllis was presumably judged highly improbable; thus we see a 90 percent use of the “exclusive or.”
2. In betting contexts, subjects tend to use an inference rule corresponding to the “exclusive or” if they do not think of the possibility of both p and q being true. The possibility of bigamy presumably did not occur to the subjects; therefore, 90 percent.
3. If, in any context, the truth of p or of q is implied to be a sufficient condition of a state of affairs, p and q will be considered a sufficient condition. That is, a rule “If p and q , then p or q ” will be used. Thus, in the context of Qs37 Nos. 19 and 20, the subjects interpreted

knowledge of Greek as well as knowledge of Latin individually to be a sufficient condition for obtaining a fellowship; therefore, they found the combination of Greek and Latin sufficient. Accordingly, they answered as if using a rule "If p and q , then p or q ."

4. The particle *or* is sometimes used not disjunctively, but as a coordinating particle (see *Oxford Dictionary*). It is then used in "unstressed positions" ("Do you want whiskey, gin, vermouth, or cakes?"). In such cases, the compatibility or other relations between p and q are largely left undetermined. Therefore, "If p and q , then p or q " is considered valid when *or* occurs as a coordinating rather than a disjunctive particle.

The answers to Qs37 Nos. 14 and 16 show in a very convincing way the absence among the subjects of abstract general rules of inference corresponding to those of symbolic logic systems—even if a rule is said to be present when only implicit or as a disposition. The awkwardness or impossibility or absurdity of temperatures being neither more nor less than 60° , or being both, disturbed the subjects and provoked long discussions. Very few reacted rapidly and consistently, as would be expected if they had applied an inference rule of a simple kind. The complexity of the answers may be taken as symptomatic of the existence of very complicated inference rules. It would, however, require much work to construct systems such that answers would fit in.

A small number of subjects (less than 10 percent) wrote down comments to their answers, and from these it can be gathered that some kinds of *inference rules* are in use, mostly referring to *or*. Thus, subject 253 answered no to Qs37 No. 15, question 4, and added, "Jack is married to Joan or he is married to Phyllis. Therefore being married to both, he cannot be married to Joan or Phyllis, for the *or* excludes one."

On the other hand, some comments suggest that their authors do not conceive of any rules but simply perceive or intuit *what is said* by A and B . The short comment of subject 303 to Qs37 No. 13, question 4, reads, "A said 'one or the other', not both." To the awkward question 4 of Qs37 No. 14, subject 338 exclaimed, "This seems somewhat ridiculous—the temperature in the same place can't have two values at the same time. However, A lost since he said 'either . . . or'."

This last comment is of interest because it suggests that its author believes in the existence of one constant meaning or function of “either-or” overruling the consideration that two temperatures at the same place is ridiculous, and having nothing to do with the contents of the disjunction.

The answers to the fellowship questionnaires indicate, however, that the expression “either-or” rarely does induce people to answer in the direction of the “exclusive or” if the content of the proposition makes the use of the “inclusive or” somewhat more natural.

In the contexts suggesting the use of the “exclusive or,” the introduction of *either* induces some more people to choose this interpretation. This holds true also for the Norwegian *enten*. On the whole, the Norwegian students seem to use their *eller* more for the exclusive disjunction than the Americans use their *or*. However, the same trends are present in the Norwegian material as in the American: a tendency to abandon the exclusive interpretation when *either* (*enten*) is left out, and when the possibility of both *p* and *q* being true is pointed out, as in the context of Abdullah’s marriage.

In any case, it is wise to infer from the answers that many *inhaltliche* considerations are relevant for the subjects when they are asked to judge inferences involving *or*. Or, to be more careful, considerations are relevant that at least in relation to certain logistic systems are *inhaltlich*.

With regard to the material covered by the questionnaires, to what extent do professional logicians have hypotheses concerning logical inference among nonprofessionals? A small number of professionals were asked to state what might be the most frequent answers to the Qs37 questionnaires. The straggling answers confirmed the impression that it is difficult and hazardous for professionals to pronounce on how nonprofessionals reason and how they use the logical connectives without having performed a series of experiments. Only, however, with close reference to experiments and tests is a terminology likely to develop that can function as a common idiom for investigators who favor different theoretical approaches.

Common Sense and Truth

The number of so-called theories of truth is—as all interested in philosophy know—very large. Less numerous are the theories concerned with the notion of truth among people who are not (supposed to be) philosophers. I shall call these latter theories common-sense (cs-) theories. There are theories about a “Volkswahrheit,” “Wahrheit der grossen Haufen,” “Wahrheit des Kindes” (Heinroth), “truth as viewed by all people” (Beatrice), “the popular use of ‘truth’” (Brandt), “‘Wahrheit’ in üblicher Bedeutung” (Carnap), “‘Wahrheit’ in der Umgangssprache” (Carnap, Tarski), “la notion commune que la conscience humaine se fait de la vérité” (Leroux), and so on. Thus enumerated these theories may seem little connected with one another, but in fact the discussions centering on formulations of this kind are carried out *as if* they all dealt with the same subject: the one is found “better” than the other, some are “refuted” by some others, and so on. Moreover, it is not uncommon to find references to “that which is limited by the bare meaning of the words *true* and *false*” (Husserl and others), to truth as revealed “wenn man einen Bauer fragen wollte” (Lossius), or to truth “if common sense had been asked to formulate” it (Marhenke). These references are observable in current discussions about “truth” and might give the impression that investigations of some sort have been carried out—for example, systematical observations of how the word *true* is used, or inquiries into the type of answers received if those in one’s non-philosophic environment are asked to define truth. This impression is, however, apt to fade away as soon as one reads some 100 theories and ob-

This article was originally published in *Theoria: A Swedish Journal of Philosophy* 4 (1938): 39–58. It has been revised for this collection.

serves how the authors contradict one another, how they fit their cs-theories into their general theories of cognition or reality, and how they seem to avoid any actual description of experiments. I think that even superficial questioning of nonphilosophers makes it hard for anyone to believe that the philosopher has got his “knowledge” about peasants’ and others’ use of the word *true*—or about the views of nonphilosophers on the notion of truth—by asking any other person than himself. If they, for example, have given their wives and their assistants the occasion to utter what they think about the matter, or if they have asked a philologist, how could they write as they have done? This is a difficult psychological problem, and I shall not try to defend any special solution of it.

This is not the place to describe the philosophical cs-theories, but to aid the inexperienced reader we shall quote some at random:

Every belief asserts that something (in the widest sense of something) possesses a quality, or is connected with something by a relation. If the belief is true, then that thing does possess the quality or is connected with something by the relation. The possession of such a quality, or the connection by such a relation is a fact, according to our definition. And if the belief is true it will correspond to the fact. . . . If common sense had been asked to formulate what is to be meant by the truth of a belief, this is probably what it would have written, just as it would have agreed to McTaggart’s definition of the falsity of a belief.

(Marhenke 1922: 169)

[D]e beaucoup les plus nombreux traducteurs fidèles du sens commun, caractérisent la vérité comme un accord de l’idée et de la réalité, une relation de correspondance entre notre pensée et son objet. . . .

(Leroux 1923: 302)

According to Richter (1908: 16) there are some characteristics of truth that are fundamental and generally accepted. Among them are “Unveränderlichkeit der Wahrheit und deren Evidenz für alle Subjekte.”

Le sens commun appelle *vraie* toute idée conforme à la chose qu’elle représente. Le vrai de ce point de vue réaliste, c’est donc l’être même. La notion de vérité répond alors à la formule scolastique: *adequatio rei et intellectus*.

(Le Roy 1930: 182)

Without saying how he has arrived at the conclusion, Le Roy declares that this theory of the nonphilosophers implies a “realistic ontology” and “the criterion of fact.”

Walker finds that objective evidence is the criterion of truth and “the only criterion which the ordinary man uses.” Objective evidence he explains thus:

We assent because we are forced so to do by the object itself, because it is the object itself and not some other object or cause which seems to have manifested itself to our mind. We assent because that to which we assent is “obvious” and we cannot help assenting.

(Walker 1910: 641)

In one respect, all nearly agree in regard to the definition of the term, for all admit that by truth is understood a harmony,—an agreement, a correspondence between our thought and that which we think about.

(Hamilton 1870: 63)

Consider again too, in this connection, the scholastic definition of Truth, which is also the current definition, the definition of popular philosophy, being that of the direct mode of consciousness as distinguished from the reflective. That definition is—the agreement of our thought of things with the things themselves.

(Hodgson 1878: 213)

Der Willensakt, welcher im Urtheil zu der Vorstellungstätigkeit hinzutritt, ist von den Stoikern als Zustimmung (*συγκαταθεσις*) bezeichnet worden, und es fragt sich nun, was diese Zustimmung bedeutet. Es ist begreiflich, dass das naive Denken an diese Frage mit der Voraussetzung herantritt, die Bedeutung der Zustimmung, d. h. der Sinn der Wahrheit müsse immer derselbe und ein für allemal bestimmbar sein.—Das ist nun aber gerade nicht der Fall, sondern eine kurze Ueberlegung beweist, dass die Wahrheit in sehr verschiedenem Sinne gemeint sein kann. Die Wahrheit eines mathematischen Satzes, die Wahrheit einer historischen Hypothese, die Wahrheit eines Naturgesetzes—sind sie durch dieselben Merkmale zu bestimmen? Man wird von dem unbefangenen Denken vielleicht diese Frage dahin bejaht finden, dass die Wahrheit unter allen Umständen in der Uebereinstimmung zwischen der Vorstellung und der Wirklichkeit besteht. Aber man wird sich leicht überzeugen, dass das schon für jene drei Beispiele nur in sehr unvollkommener Weise zutrifft.

(Windelband 1914: 196)

[W]ir haben darin vielleicht den vollständigsten Ausdruck der naiven Weltanschauung, welche den vorstellenden Geist in einer Umwelt befindlich annimmt, die sich in ihm irgendwie wiederholen soll, und alle die sinnlichen Tropen, mit denen die Sprache den Erkenntnisprozess bezeichnet—abbilden, spiegeln, erfassen, begreifen usf.—zeigen, aus der Tätigkeit der verschiedenen Sinne entnommen, nur die verschiedenen Arten, wie eine solche innere Wiederholung des aussen Wirklichen vorgestellt werden kann . . . “die transzendente Wahrheit”—so mag dieser erste und naive Wahrheitsbegriff genannt werden—ist in ihrer ursprünglichen Bedeutung nicht aufrecht zu erhalten.

(Ibid., p. 197)

Unbeirrt durch solche Erwägungen hält das naive Bewusstsein jenen ersten Wahrheitsbegriff fest, und soweit es darin nicht schwankend wird, sprechen wir nach Kants Vorgang vom Dogmatismus der Erkenntnislehre, welcher ohne weitere Kritik das Gelten seiner Vorstellungen als ein Erfassen oder Abbilden der Wirklichkeit behauptet.

(Ibid., p. 214)

I think that such formulations are interesting objects for psychological and sociological research, and it is mainly as such that I intend to deal with them here. Looking at the truth theories as a naturalist looks at some interesting flowers, one may ask, How do truth theories evolve? What determines the choice of theories among the professional philosophers? Which traits of philosophic culture favor the production of truth theories? Is it possible to find laws that hold for the choice of theory? What distinguishes truth theories from an average theory of contemporary natural science? Is it possible to domesticate “truth theories,” and if this is possible, which relations then hold between variation under domestication and variation in nature? To get some material with bearing on these and similar subjects, I decided to try to produce truth theories “experimentally” by asking people without philosophic training all sorts of questions that would in a natural way lead them to speak about ‘truth’. A lengthy monograph now to be published discusses this and similar subjects. I shall in this article indicate how they are dealt with.

Without a clear idea of what the philosophers aim at when they construct theories of truth, it is difficult to take a view of what they call the nonphilosophers’ opinion of the truth notion. How is it possible to control what the latter say, ignoring this?

I have never heard a nonphilosopher state something similar to a “view on the notion of truth” without being urged to it. To collect material for this subject it is therefore necessary to *construct situations* to which it is probable that people react with statements analogous to “opinions on the truth notion.” Of such reactions, certain types are more valuable than others for purposes of comparison. The statement “One will never find the truth” is especially valuable if the person has also given a definition of truth. If he has not, we do not know, for example, whether by “truth” he means “statements firmly believed by all persons,” “agreement with reality,” “Reality,” or something else. Utterances such as “*True* means agreement with reality” and “The common characteristic of what is true is that it serves life” are valuable too because of their close resemblance to basic formulations of philosophers: philosophic definitions of truth—the nuclei of truth theories. It is of interest to know what things a person calls true after having heard how he defines truth. The cs-theories do not usually mention this last subject, but I think it advisable to know something about how it might control them. Considerations of this kind forced me to adopt a questionnaire method, to try to stimulate people with verbal utterances, for example, of questions about “the notion of truth.” Actually, I used a questionnaire method with the character of personal interviews, assisted by standard lists of questions that functioned as starting points for discussion.

Experiments show that the person thus stimulated probably answers with “definitions” and that his reactions generally have no *specific* nonverbal traits: he may run away, laugh, fall into a stupor, look down at the floor, but these reactions also occur in situations in which questions about the notion of truth are lacking as stimuli. *Verbalized* unities of behavior should therefore form our first and most important subject. My first method for detecting such unities was to ask a direct question such as “What is the common characteristic of what is true?” and then to examine carefully in which possible unities of verbalized behavior the respondents’ answers occurred. This was done by letting the person talk without trying to lead the conversation by posing any further questions concerned with truth. The subjects touched upon by the person were adopted as subjects for further questions. All *Einfälle* of the person were written down to get a picture of the verbalized behavior unities thus connected with the reactions to my introductory question.

After using this method with about sixty respondents, I gave it up and

adopted a rigid questionnaire method. The main reason for the change of method was to get valuable statistical material with a bearing on all basic philosophic questions discussed in "truth theories." The value of such statistical material is proportional to the stability of the conditions under which tests are carried out. I consequently tried to standardize the situations. This was done by standardizing the *questions*, leaving less room for undirected explorations. During the collection and interpretation of the material, supplementary schedules were constantly worked out to meet the need for information not previously desired. Not all questionnaires concerned the notion of truth: a great many truth theories speak promiscuously about what is true, right, correct, certain, false, wrong, erroneous, and so on. I therefore worked out questionnaires each of which was concerned with one of these expressions. For the sake of brevity, in the following I shall refer to the different notions as "S-notions" or as "truth and similar notions." Three hundred people were examined according to the standardized questionnaires. The average duration of the examinations was about one hour. No one was examined for less than ten minutes, and some people were examined for more than ten hours.

To give an impression of the questionnaires used, I shall indicate the contents of an "average" questionnaire: (1) Request for examples of something true and questions about whether the examples put forth have a common characteristic. Request to define 'true'. (2) Questions concerning the existence of something absolutely true. Requests for examples. (3) Question regarding the person's possible familiarity with the subjects under discussion.

All conclusions arrived at are based on sampling: in the field subjected to investigation no other method is possible. It is impossible to ask *all* people about truth, impossible to inspect *all* produced truth theories. *None of my conclusions I think in any way secure*—I predict that a considerable percentage of the statistically obtained correlations (say, 15 percent of them) would prove deceptive if the sample size were enlarged from 300 to 1,000 or 5,000. There are people who think that clear perception of this limited security must imply a severe judgment on the scientific worth of the correlations. I cannot agree with them: our daily life-knowledge and much of our psychological and sociological knowledge are of the same type. The difference is often only in the formulations: absolutistic formulations very often

predominate in fields in which careful statistical formulations should prevail. If 80 percent of sociological predictions based on correlations found in a sample of 100 individuals are confirmed in a sample of 1,000 individuals, I think the predictions are of a high standard. In the last part of this article, I have allowed myself to state very far-reaching theories concerning truth theories. It should be unnecessary to point out that one may accept the statistical results of my work without in any way accepting my theory on the “dynamics of truth theories.”

The protocols written by the examiner or (less often) by a respondent contained 500 “definitions” of the notion of truth (or similar notions) produced by 250 respondents. As definitions, I classed statements of a very general character resembling (or being identical with) what are called definitions by the “professionals” (the philosophers who create and publish truth theories).

The ages of the respondents ranged from 12 to 65, their school training from none to baccalaureate. No person who was studying or had studied philosophy at the university was included. Exceptions were respondents who had read two or three books on philosophy but had never read or heard anything about truth theories (according to their own account). The following list contains the definitions of a few of the respondents, together with the examiner’s questions. Many of these questions, *Q*, do not come from the questionnaires but were determined by previous answers, *A*, of the respondent.

Q: Is there anything absolutely true?

A: (21-year-old school senior, Norwegian “gymnasium”) If it agrees with one’s own feelings and sense impressions.

Q: What are some common characteristics of things that are absolutely true?

A: (17-year-old school senior) What cannot be otherwise.

Q: What is the common characteristic of that which is true?

A: (21-year-old, baccalaureate) That it is real.

A: (16-year-old school senior) That it is the absolutely logical.

EMPIRICAL SEMANTICS AND 'TRUTH'

A: (15-year-old, less than ten years of schooling) The common characteristic of all that is true is that it is in agreement with reality.

A: (17-year-old school senior) Subjectively: by its effects on the individual; the characteristic of the true is that it satisfies all parts of one's critical intelligence.

Q: What is the common property of that which is true?

A: (15-year-old, less than ten years of schooling) That one can prove it.

Q: What is the common property of true statements?

A: (19-year-old, less than ten years of schooling) That they are said with a certain strength.

Q: What is the common characteristic of that which is true?

A: (16-year-old school senior) That it really exists.

Q: Why do you use the word true?

A: (16-year-old school senior) It is something that we have been taught to believe.

This short list (chosen at random) may already convince the reader that many different views of the truth notion are represented. One may classify the definitions into as many groups as one wishes: 480 out of the 500 definitions were different with regard to formulation. Certain tests indicate that most formulations were viewed by the respondents as having different and incompatible meanings. We shall here briefly mention three methods of grouping the definitions. The first method (Gr1) leads to groups comparable with the groups constructed by philosophers who classify truth theories (correspondence, coherence theories, and so on). About 30 percent of the definitions could not, however, be satisfactorily placed in any philosophical group. According to Gr1, the definitions fall into about forty-five main groups. More than half of the 500 definitions (of the "standard material") cannot easily be classified into any of these groups: they may equally be said to belong to two or more of the groups or to belong to none of them.

Of the Gr1 groups, some may be of interest to the reader: Gr1.1 in-

cludes all definitions according to which truth means agreement (accordance, *Übereinstimmung*) with reality (or “the real,” “things,” “the thing spoken of”). A considerable percentage of philosophers are of the opinion that this is the definition *adopted* by nonphilosophers or that nonphilosophers *implicitly accept* it. This group is fairly well represented among the “amateurs” (16 out of 500 definitions), but there are other types of definitions that are more common among them, and, what is more important, no Gr1 group contains as much as 15 percent of all definitions. It is a waste of time to argue that when respondents say, for example, “True is what is so,” they mean the same as when they say “True is what agrees with reality.” Such identifications may in some cases be justifiable, but generally they are not. Consequently, no definition of truth can be said to express “the nonphilosophers’ view of truth.” There is no such view. One can just as well (or perhaps even better) speak of *the* philosophers’ view of the truth notion. Statistical analysis of the *examples* of truths put forward by nonphilosophers points to the same conclusion.

The most frequent Gr1 group of definitions is the one according to which an *S*-notion is defined as something that can be proved or that actually has been proved; 57 out of the 500 definitions can be said to belong to this group. It can be said to be a low-education group: the greatest frequency of this definition occurred among respondents with less than ten years of school training. Only 1 out of 400 definitions adhered to by professionals could be placed in the “proof” group.

Next to the “proof” group, many other groups can be placed, and among these the “agreement with reality” group. These two groups’ relative frequency can be distinguished one from the other only by adopting rigid definitions of “frequency.” There are several definitions of value: one may investigate the frequency distribution among respondents of *all* classes of age and education or among certain of them, thus distinguishing several types of nonphilosophers. Or, one may calculate “frequency points” by which respondents who put forth several definitions as equally or nearly equally good are distinguished from those who put forth but one definition.

According to a grouping principle called Gr4, the definitions are classed in two groups. The principle is founded on the difference between definitions with reference to “something human” (Gr4.2) and definitions

without reference to "something human" (Gr4.1). The first group of definitions tends to place man at the center of attention; the second evades mentioning anything connected with man and his activities. Accordingly, we call the formulations of the first group homopetal and the formulations of the latter homofugal. Examples of marked and obvious homopetal definitions are "(True is) what I perceive directly by my senses," "As a rule it sounds natural," and "No one is able to change it." Examples of homofugal definitions are "what is so," "the facts," and "what has happened."

According to the sayings of most philosophers (with fifty cs-theories taken into account), Gr4.1 should occur more frequently. This is not the case, however. Only 16 percent of the amateurs' definitions belong to Gr4.1 whereas 32 percent of 200 definitions put forward by philosophers belong to it. Curiously enough, the group Gr1.1 ("agreement with reality")—*also imputed to the nonphilosophers*—is the most frequent Gr1 group among the professionals (with 400 definitions in philosophic literature taken into account; definitions of "formal truth," "mathematical truth," and so on, are not included among the 400).

According to Gr6—the third principle to be mentioned here—definitions are classified according to the manner in which the respondents, by using their formulations in discussions, would be able to discern truths. How many factors have to be taken into account to identify them? If a person states that "agreement with reality" is the criterion of truth, one may say that he, *according to his formulation*, must take two factors into account: there must be a relation of agreement, and there must be a reality. It was found that the number of factors to be taken into account increases rapidly with the degree of education of the person, the correlation being much closer than in the case of Gr1 groups of definitions. The average number of factors varies for each class of age and education from 1.5 (those under sixteen years old) to 2.5. The corresponding average value of 200 definitions proposed by philosophers was 3.0.

The reader may ask whether one may look upon the definitions as *real opinions* of the respondents or whether they are mere *Einfälle*, mere words occurring to them during examinations. Various things point to the conclusion that in the majority of cases the definitions are opinions representative of the people holding them. They are the "solutions" of the problem as viewed by the respondents.

Some respondents mean that “truth” and similar notions are ethical notions. Statements such as the following are not frequent among the professional truth theorists, and they are consequently excluded from the lists of their “definitions.”

“(The common characteristic of what is right is) that conscience does not protest against it.”

“True is what conscience says.”

“Truth is the opposite of lie.”

“What is untrue is always decorating itself with a circumstantial speech.”

The relative frequency of moral views on what is true decreases with increasing age and education, but there are people who have received academic education in philosophy and nevertheless entertain such views.

Classifying the respondents by age and school training (“education”) shows that, statistically, younger and less-educated respondents are inclined (on average) to prefer different types of definitions from those most frequently used by older or more educated respondents. The preference is one of degrees. No type of definition appears to be exclusively adhered to by a single class of people. This holds good for the more frequent types of definitions.

There is no evidence to support the view that philosophic education radically changes a person’s attitude toward definitions. This is seen when comparing the types of definitions chosen by people without any philosophic school training with the types chosen by people with philosophic school training. Concluding formulations are retained, whereas arguments change.

Among the most frequent Gr1 groups, Gr1.1 (agreement with reality) shows no marked correlation with age or education; the others are, on the other hand, decidedly correlated with low-education groups and, to a lesser degree, low-age groups. This means that they are much more frequent among respondents in the 13–15 and 16–19 age groups than among those in the 20–30 and 31–65 age groups—or that they are much more frequent among people with 0–10 years of school training than among people with more training.

About 15 percent of the people whose opinions on "truth" (and similar notions) were collected did not give any "definition." The thirty-three people who can, with relative ease, be classified and who belong to this group can be placed in two categories: (1) those consistently denying or doubting the existence of any adequate definition or of any common characteristic of what is true (six persons belong to this class); and (2) those who seem to try to find formulations of the type called definitions but who do not arrive at any (twenty-seven people). Most of them may perhaps be said not to "understand" the questions put forth by the examiner.

Respondents who deny or doubt the possibility of any definition do this for much the same reasons as those found in philosophic literature, as the following examples suggest.

Respondent 15 distinguishes between the existence of a common characteristic from an "objective" view and from other points of view. "They (statements I call true) have the common property that I accept them as true from my individual point of view. From an objective point of view, certainly none."

Respondent 32 rejects the possibility of a common characteristic but states that "one cannot at all say: something *is* true."

Respondent 214: "Every definition of truth must be more or less subtle. One can define mathematical truth. That is one thing. From the point of view of natural science another thing, and then come facts such as: I am sitting here. There are many kinds of true things. But to find a word that covers all things I think is quite impossible—and if a man so ingenious as to discover such a word should exist, I would look upon his effort as perfectly aimless."

Other respondents claimed that they had to "go around in circles" to define truth.

The questionnaire method is particularly open to influence by suggestion. During the examination, I sometimes had the impression that the person might have been led to believe in the existence of a common characteristic of what is true by the fact that the first question read, *What is the common characteristic of that which is true?* I therefore decided to use different versions of questionnaires, some of which included statements suggesting that there can be no common characteristics. Statistical analysis of the results shows that there is no evidence favoring the assumption that respondents are easily influenced to acknowledge or to deny the existence of a common characteristic.

If a philosopher defines true statements as “statements belonging to the class c ,” it is to be expected that if other statements (for example, *probably*-statements) also belong to class c , he declares the latter to have the same meaning as the former. If he does not, the definition is inadequate. It was found that the respondents defined “true” in much the same manner as certain other expressions, for example, “right.” The frequency distributions of definitions belonging to the different Gr1, Gr2, and Gr6 groups are closely related, the standard deviations from the average distributions being small. This, in turn, supports the view that their function (“use . . .”) is similar. In philosophic literature there has been a tendency to neglect all notions closely related to that of truth, and to write as if statements such as “it is true” should have a function clearly distinguishable from all other statements (for example, “it is sure,” “it is right,” “it is known,” “it is so”). Statistical analysis of the respondents’ answers makes it almost impossible to believe in a specific, observable difference of function in such cases. No specific trait that is held to belong to the truth notion (unrelatedness to time, etc.) seems to belong to it otherwise than by philosophic tradition. This being the case, I think it necessary for the development of our knowledge about S -notions and “opinions” to neglect methodologically theories that do not have any other support than such tradition.

Most questionnaires included questions such as the following: Do you distinguish between something true and something absolutely true? Is there anything absolutely true? Give some examples of absolutely true statements. The correlation between belief in “something absolutely true” and “something absolutely right” (and so on) was so high that such notions (“absolutes”) need not be distinguished in formulating the study’s main conclusions. These conclusions included, for example, the finding that belief in “absolutes” is much more frequent than disbelief. Only two people thought the question of the existence of absolutes was “meaningless.” The relation between frequency of belief, disbelief, and other standpoints is 70:20:10. Very few people changed their views with regard to the existence of absolutes during the examination. The suggestibility is small. There are close correlations between belief in absolutes and age/education—disbelief increases steadily with age and education. Even among people less than sixteen years old, there are, however, as many as 15 percent who are “sceptics.” How many there are in other

countries or how many there will be in ten years, I leave to others to estimate.

There is much evidence in support of the view that females have a greater tendency to believe in absolutes than do males. Lack of space makes it impossible here, as in connection with other statistically obtained results, to formulate our conclusions carefully. Exact statements with quantitative values are meaningless unless one can describe exactly how they have been arrived at.

Reading philosophic discussions on the notion of truth, one becomes accustomed to expect that advocates of this or that type of definition believe in absolute truth, whereas one expects that advocates of a different type of definition doubt or deny the existence of absolutes. Statistical investigations support the assumption that there are correlations between types of definitions and their authors' standpoints toward the existence of absolutes. It is apparent that one may, with a certain amount of probability, forecast that if a philosopher or a respondent adheres to a certain *Gr1* group (among the larger ones), he will favor a certain view of the existence of absolutes. In this, as in other connections, our prognoses are intended to be valid only in milieus with the same average properties as those of our philosophers and our respondents today.

The request for examples of something true (or of something absolutely true or of correct statements, etc.) brought into existence 1,000 "truths" that could be analyzed statistically. The types of examples varied slightly with the respondents' age and education as well as with their definitions. Individual differences were considerable: the "things" relevant to the true-false distinction were conceived in a fundamentally different way by different people. That the "truths" of one person would be considered "errors" by another was only to be expected. In spite of this, one may say that those giving apparently conflicting definitions of the notion of truth do not tend to choose conflicting types of examples.

What do respondents think of other respondents' answers? Will they, for example, think that the definitions of others "mean the same" as their own? Will they accept the notions of others or will they behave as philosophers? To address such questions, I confronted the respondents with definitions of other respondents and of philosophers, and with some of my own, the latter written down as *Einfälle*. More than 1,300 verdicts were analyzed.

On average, 77 percent of them were critical in cases of the definitions concerned being one put forward by another respondent. The standpoints toward the definitions of philosophers were on the whole slightly more favorable: 55 to 60 percent critical and 25 to 30 percent sympathetic. The seventy-two definitions written down as *Einfälle* were treated like those of the respondents. Very few (out of 470) definitions were tolerated by more than 75 percent of the people requested to consider them.

Having found the correlations between age, education, and standpoints toward the "truth-problem," I thought it worthwhile to try to find other correlations with such standpoints. During the examination of the respondents, one got the impression that their argumentation gave a good picture of at least some of their inclinations. It was quite another thing, however, to collect sufficient statistical material to support such impressions in a scientifically sound way. Because of certain practical difficulties, only one characteriological test—a test of "confidence" and "suggestibility"—was carried out. Schematically described, it consisted of the respondent's being invited to smell three test tubes containing different substances (*A*, *B*, *C*) with characteristic odors. He was then given fifteen other test tubes that were said to contain weak solutions of *A*, *B*, or *C* but that actually contained nothing but distilled water. For each tube, the respondent was asked: (1) Do you smell anything? and (2) How sure are you? If he said he did smell something, he was asked: (3) What do you smell? and (4) How sure are you? An index of suggestibility was worked out in the usual way. The degree of confidence was calculated thus: the respondent was asked to indicate how sure he was by using either his own words or a set of expressions written on a list such as the following: (1) perfectly sure; (3) not quite sure; (5) as likely to have been mistaken as not. A confidence scale was worked out on which 1 ("perfectly sure") was fixed as 100 confidence points (c.p.) and 5 as 0 c.p. The correlation between confidence (as defined in this test) and standpoint toward absolutes was marked: disbelievers in absolutes avoided the expressions commonly held to indicate "great confidence." The correlation between suggestibility and standpoint toward absolutes was less marked. Taking the general behavior of each respondent into account, one sees clearly that numerous complicated factors are operating and that one has to be extremely careful in interpreting the material.

The questionnaire method proved adequate for our purpose of creating truth theories "experimentally." It is apparent that all aspects of truth theories as they appear in philosophic literature can be reproduced. The debates of philosophers were copied by bringing some of the respondents together and letting them discuss their own answers. To compare truth theories put forth by amateurs with those of professionals, I worked with a "standard material" consisting of the truth theories of about 165 philosophers. This material I regard as a *fair sample* of truth theories. Most of the results of the comparison cannot be stated in a few words. Here I can only state some of the simple results in a rather crude and inexact way:

No type of definition found among the philosophers is lacking among the respondents—if one permits oneself to neglect 5 percent of the professional definitions that include exceedingly difficult words apparently untranslatable into the vocabulary of everyday speech (the definitions of Hans Driesch and others). No type of standpoint toward the possibility of defining the truth notion is lacking among the amateurs, nor do we find any type of standpoint lacking toward the existence of something absolutely true, toward verification, and toward the principle of the excluded middle. The philosophic *cs*-theories seem therefore to lack every empirical foundation. Only if one emphasizes minor differences and the bulky comments generally connected with statements of the conclusion can things be otherwise. It is easy to say that the respondents do not understand what they talk about, that they do not grasp the essence of philosophic questions. Observing their behavior in cases in which examination and discussion lasted several hours or extended over two years, I came to the conclusion that their opinions are deepened and consolidated whenever they get the *time* to work them out. In such cases, the main features of the first answers are generally retained. How do we, on the other hand, feel sure that philosophers know what they talk about? If respondents put forth opinions similar to philosophers; if two opinions, *A* and *B*, most often found together among philosophers are also found together among respondents; if arguments in philosophic literature in favor of *A* occur as arguments in favor of *A* in discussions among respondents; if, in short, the general behavior with bearing on truth theories is similar in both cases, then how can we place the professionals in an exceptional position?

Although many profound things are said in favor of truth theories, there are also many definitions containing references to exceedingly subtle distinctions never (perhaps) to be found among respondents. How, though, are these profundities treated by philosophers who do not adhere to their author's main views? They are brought down to very simple and prosaic things wholly within the reach of amateurs such as the respondents. It is worthwhile to study how the truth theory of one philosopher is described by other philosophers and to note how the truth theory is simplified and how discussion of it deals only with its coarsest and simplest features: the nucleus of the discussion. The statements that really invite the others to debate are simple and easily found among respondents between the ages of fourteen and seventeen.

Such considerations inevitably lead to the question, Does the philosophic discussion about truth develop as scientific discussions do; is there any progress owing to accumulated knowledge and experience? The question has to be answered with a no, I think. Already the discovery of all the basic types of formulations among respondents of ages fourteen to seventeen indicates that they undergo no further significant development: basic formulations are retained through all classes of age and education and ultimately made the center of philosophic discussions involving, for example, a definition of truth. The clumsiness of many of the respondents' expressions is replaced by the profound ear of philosophic style, and arguments are brought from more distinguished quarters, from contemporary scientific or ideological currents—but the concluding statements are the same.

How is it possible, one might object, that one definition is found more *reasonable* than any other if there is no development owing to insight? I think one factor is very strong: habit. Probably very few people who develop into philosophers and authors of truth theories are at the starting point acquainted with many truth theories. They get used to stating and arguing for a certain view. When they later on become acquainted with new theories, these are found less reasonable because they offend some already established habit of thought or expression. This process is clearly seen among respondents who are examined several times or who discuss their definitions with others. The following experiment was especially interesting: Three respondents were each confronted with three definitions of truth. None of them accepted the definitions, but in spite of this, each per-

son was instructed to *defend* one of the definitions against attacks by the other two. All three people were invited to attack the definitions of the others. They did this very unwillingly, professing that they did not understand the definitions and so on. In the discussion that followed, however, the arguments in favor of the first definition, "true is what serves life," were of the kind found in pragmatic literature; the arguments in favor of the second, "true is what is in agreement with reality," and the third, "true is what can be controlled by one's senses," were of the kind found in philosophic discussion of just these kinds of definitions. It was interesting to note that the respondents consciously or unconsciously tried to assimilate the definition they were forced (by pride, etc.) to defend, cleverly making the expressions of it in some way relevant to their own opinions, which they entertained with much fervor and tenacity. By this mechanism I think it is possible for anyone to defend a statement that he once, by chance or at least without acute reasoning, happened to adopt: it grows more and more "reasonable," more and more "obvious." It should be superfluous to admit that there are many exceptions to this law of development.

There are subjects under philosophic discussion that in many cases seem to flourish because of opinions that function like the opinions referred to above: opinions about the "ultimate nature of reality," "the possibility of living without illusions," "the objectivity of moral Truths," "the possibility of arriving at something that cannot be attacked by any sceptic," and so forth. They seem to determine, indirectly, basic views that in turn inspire the detailed opinions on the notion of truth. (See, for example, the discussions between F. C. S. Schiller and Bertrand Russell in *Journal of Philosophy, Psychology and Scientific Method*.)

It is not my intention to state that *all* published theories of truth are inspired by some vividly affective opinions concerned with subjects foreign to the "truth-problem." Just as occurs in religious systems with long traditions, however, there are always discussions going on about opinions, once a symbol of their advocates' deep affective tendencies, that later on are discussed simply because it is a good tradition to discuss them. The affective contents and symbolic character are no longer recognized.

The comparison between published truth theories and those of "amateur" respondents leads to results that cannot possibly stimulate the scientific in-

terest in new theories: the whole matter does not seem to be worthwhile. Such a conclusion is justifiable, I think, as long as one speaks about the basic formulations, the definitions of truth and similar notions, and not about the discussions found in papers on the truth notion, which are but loosely connected with the nucleus of the philosophic “truth-problem.” There are problems and disciplines of great scientific interest that only the force of tradition has linked with the philosophic “truth-problem”:

1. Problems regarding the development of hypotheses in science—why this or that theory was accepted, and so on; the function of scientific discussion, as revealed in this or that science in this or that period.
2. Problems involved in the study of how opinions of groups come into existence and how they die out; public opinions, ideologies, and so on.
3. Logistic problems related to expressions of opinions on opinions: formulation and axiomatization of expressions such as “prove” and “imply,” for example.
4. Practical proposals to standardize and sharpen the expressions of opinions on opinions when greater accuracy is thought desirable; proposals to avoid this or that expression or to use the expressions e_1 and e_2 as synonyms in certain discussions, etc. Such proposals can be justified without reference to the philosophic “truth-problem”: the later “problem” is reduced to questions belonging to (1), (2), (3), or (4) as soon as an attempt is made to state it clearly.

Logical Equivalence, Intentional Isomorphism, and Synonymy as Studied by Questionnaires

In Memory of Gerrit Mannoury

In recent discussions on synonymy among logicians and philosophers who use logical analysis as the main tool for inquiry, there has not been much reference to observational data and techniques. It is therefore not to be wondered that there is a considerable lack of clarity in the treatment of the relationship between conceptual constructions and empirical research by means of questionnaires. In the following, we shall discuss this relationship, keeping in close touch with the important contributions to the study of synonymy by Benson Mates.

Logical Equivalence and the Inconceivability of Difference as the Condition of Acceptance

Among logicians, it is common to think of synonymy as a narrower relation than logical equivalence: if two terms are synonymous, they are of necessity logically equivalent; but if two terms are logically equivalent, they may well be heteronymous. If this trend of usage and opinion is accepted, it will be a sign of the failure of a concept of synonymy if, according to that concept, all logically equivalent sentences are synonymous.

Benson Mates, in his article "Synonymy" (1950: 213), offers "some comments on other people's views" and describes certain concepts proposed in my *Interpretation and Preciseness* (1953). These concepts are called Qs1A-synonymy, Qs1B-synonymy, Qs2A-synonymy, and so on; Qs1 and Qs2

This article was reprinted with permission from *Synthese: An International Journal for Epistemology, Methodology, and Philosophy of Science* (Dordrecht, Netherlands: Kluwer Academic Publishers) 10 (1958, 1959): 471–79.

refer to the names of certain questionnaires, and the letters *A* and *B* refer to the rules regarding how the answers to the questionnaires are to be taken (for example, as confirmatory or disconfirmatory evidence for the presence of Qs1A-synonymity, Qs1B-synonymity, and so on).

Mates finds it likely that according to one of the concepts introduced by means of questionnaires and the rules of confirmation for the answers to them, "all logically equivalent sentences would be synonymous" (1950: 215). The concept that Mates may have in mind here is Qs5B-synonymity. It has been introduced approximately as follows:

Two sentences, *T* and *U*, are said to be Qs5A-synonymous in relation to a pair of texts *S*₁ and *S*₂ and for a person *P*, if and only if *P* answers negatively to the crucial question of a questionnaire of the kind Qs5 with *T* and *U* as parts of the texts *S*₁ and *S*₂.

The crucial question for Qs5 is, Can you imagine circumstances (conditions, situations) in or by which you would accept *T* and reject *U*, or vice versa?

Two sentences, *T* and *U*, are said to be Qs5B-synonymous in relation to a pair of texts *S*₁ and *S*₂ and for a person *P*, if and only if they are Qs5A-synonymous in relation to that pair of texts and that person, and if *P*'s answer is an answer to the crucial question of Qs5 as this question is interpreted by the framer of the questionnaire.

In order to subsume an answer to questionnaire Qs_x under those requirements establishing Qs_xB-synonymity, we must accept as tenable not only the hypothesis that the answer is meant to be negative, but also the supposition that the person tested interprets the question, *grosso modo*, as does the analyst.

The construction of Qs5 was inspired by philosophical writings and debates in which the inconceivability of a difference as the condition of acceptance seems to be taken as a criterion of synonymity, or of a very small distance of meaning.

In the following, we shall discuss some of the difficulties that emerge when the discussion of synonymity as conceived by the logician and philosopher Benson Mates is compared with the efforts to study synonymity, or more generally, meaning-distance, by means of observations

under standardized conditions. In the first part of this article, our attention will be focused on the question of how logical equivalence is related to synonymy when the questionnaire Qs5 is used in the meaning-distance study.

The empirical, soft-science methodology underlying the questionnaire approach does not require that one should attempt to find a definition (in the sense in which *definition* seems to be used in articles by Tarski and Mates). Tarski asked for and proposed an “adequate definition” of truth agreeing at least to a large extent with ordinary usage. Mates says that “there is no doubt that this notion, however vague it may be, is of considerable philosophical importance, and a good definition of it is greatly to be desired” (1950: 208). In a footnote, he adds: “As I use the terms, ‘to find a plausible definition of the term’, ‘to explicate the notion’ and ‘to define the notion’ denote the same process.”

It is our view that the range of phenomena more or less vaguely and ambiguously referred to by the term *synonymy* is so great that there is no reason to expect that a single, carefully introduced concept could somehow be made to cover *the* essential features of those phenomena. The studies by means of questionnaires, which Mates refers to, are inspired by the belief that there should be developed in relation to research techniques a large number of concepts of smallness of meaning-distance. Only after some empirical work has been accomplished with hypotheses framed by means of these concepts should the question be taken up of how one can reduce the number of concepts to a minimum. It seems that Mates, on the contrary, is mainly interested in discussing concepts that in an outstanding way might express the essential features of what competent people have so far classified as cases of synonymy. Among the features that Mates considers essential is the one that not all logically equivalent sentences are synonymous.

Mates seems to have asked the following question: is the concept of Qs5B-synonymy such that all pairs of logically equivalent sentences are ipso facto synonymous?

This formulation of the problem is misleading, for the following reason. The concept Qs5B-synonymy should not be viewed as a concept of synonymy in the narrow sense of an *adequate definiens* or *explicatum* of “synonymy,” but as a concept belonging to an open family of concepts of smallness of meaning-distance that is (at the present time) fruitful in em-

pirical studies of the heterogeneous phenomena vaguely and ambiguously referred to as synonymy.¹

Complex designations such as Qs5B-synonymy and questionnaire-synonymy, which contain as subordinate parts (meaning, as designation fragments) the term *synonymous* or *synonymy*, are to be considered as technicalifications of "synonymous" and "synonymy," and not as definitions as in the terminology of Tarski or Mates.

Therefore, if the concept of Qs5B-synonymy is accepted, and all logically equivalent sentences should turn out to be Qs5B-synonymous, this would not warrant our deducing that all logically equivalent sentences are synonymous.² The acceptance of Qs5B-synonymy does not imply the acceptance of it as an adequate definition or even the acceptance of the possibility or desirability of constructing adequate definitions.

Let us then proceed to the question "Is it not to be expected that all logically equivalent sentences as a matter of fact turn out to be Qs5B-synonymous?"

Sentences of the skeletal form "*T* is Qs5B-synonymous with *U*" might be taken as abbreviations for "*T* is Qs5B-synonymous with *U* for all persons, in relation to all texts." If the sentences are used within a discussion concerning a definite investigation that involves a class of persons and texts previously mentioned, "all" might be taken to refer to all members of this class. If not, it is much less obvious what "all" might refer to. The possibility that "all human beings" is meant may be discarded, because hardly any expressions would then ever fall under the concept. For the sake of illustration, let "all persons" stand for "all students at the University of Oslo" and "all texts" for "all English textbooks used by those students." Since Mates (1950) quotes Carnap, let "logical equivalence" be understood in the sense that Carnap in his *Introduction to Semantics* (1942) attributes to *L*-equivalence, that is, mutual *L*-implication.³ It is defined in relation to a set of rules, not to use occurrences of expressions.

Suppose, now, that two sentences *T* and *U* are logically equivalent in a language model *L*, which is supposed to cover the natural language of person *P*, belonging to the class of persons under consideration. By saying that *T* and *U* are logically equivalent (in the sense of Carnap), we do not imply that anybody knows or ever will know that they are logically equivalent. Nor is it implied that *T* and *U* have ever been used before appearing in the

texts selected in Qs5. No previous use occurrences may have been produced. Consequently, logical equivalence between T and U does not imply that they have ever been used in accordance with or in disagreement with any explicit or implicit semantical rule. If T and U have been used, they may have been used in any way whatsoever. Two logically equivalent sentences in L may, for example, happen always to have been used as antonyms.

If, now, P is confronted with a questionnaire Qs5, and if the logically equivalent sentences T and U are used as crucial sentences, it may or may not turn out that they are Qs5B-synonymous for him in relation to the pair of texts chosen. There is, in other words, no guarantee that logically equivalent sentences are Qs5B-synonymous. In spite of this, it may be methodologically justifiable tentatively to assert as a soft-science working hypothesis that all pairs of logically equivalent sentences are Qs5B-synonymous.

There may be high positive correlations between the two properties within important classes of sentences and of people, or there might be in the future a well-established hypothetico-deductive system covering these phenomena, from which a theorem implying the hypothesis could be deduced. Considering the absence of an established correlation, the above-mentioned hypothesis, if formulated as an assertion, would seem at least premature.

Let us then suppose that P believes that T and U are logically equivalent (in the sense of Carnap). It is to be expected that this highly increases the chances that they are Qs5B-synonymous for him—in general or at least in relation to certain wide classes of contexts. If they happen to be Qs5A-heteronymous, might we then say that P 's answer to Qs5 is a result of mistakes in logic or of misinterpretation⁴ of the questions? I do not think so.

Let the two sentences, T and U , be “ 2^{10} is less than 1,000” and “1,024 is less than 1,000.” Our hypothesis is that for at least 5 percent of those who believe firmly that T and U are logically equivalent, they are at the same time Qs5B-heteronymous. The author of this article belongs to this 5 percent. In the way that I and many others have been taught arithmetic, it is necessary to do some calculations to establish that $2^{10} > 1,000$, but not to establish that $1,024 > 1,000$. I believe that I am able to conceive of mistakes having been made in any calculation. Therefore, I believe that I am able to conceive the possibility that 2^{10} is less than 1,000. This I am able to do in

spite of my conviction that 2^{10} is greater than 1,000. " 2^{10} is less than 1,000" and " $1,024$ is less than 1,000" are consequently Qs5B-heteronymous for me, because I can conceive of the possibility of a text showing that 2^{10} is less than 1,000. If this text precedes a use occurrence of " 2^{10} is less than 1,000," I would accept it but still reject " $1,024$ is less than 1,000."

For persons for whom the above exemplifications of T and U are Qs5B-synonymous, "Philip believes that $2^{10} < 1,000$ " and "Philip believes that $1,024 < 1,000$ " are very likely to be Qs5B-heteronymous. Thus, the complication discussed by Mates does not arise in the way he describes, since the conceivability of a difference in cognitive acceptability is taken as a criterion in questionnaires of the kind Qs5. This does rule out that Qs5B-synonymity is not too wide a concept for certain purposes. The usefulness of the concept of Qs5B-synonymity is apparent only as part of a conceptual structure in which similar, but not identical, concepts serve similar, but not identical, purposes.

If "logical equivalence" is not taken as referring to rules but to a kind of relation between sentences in use, the relation between logical equivalence and Qs5B-synonymity might well be very intimate. In no case, however, does it seem convenient to use only those concepts of logical equivalence such that logically equivalent sentences could not possibly be Qs5B-heteronymous.

Intentional Isomorphism

One of the main trends in the use of the expression "expresses the same assertion as" is such that explications in the direction of intentional isomorphism seem more adequate than those in the direction of logical equivalence.

An important question is how one could best study empirically this trend of usage, and construct concepts in line with it. The well-founded rejection by Carnap, Mates, and others of a general identification of synonymity with logical equivalence or with identity of the conditions of confirmation—in those senses of these terms that they have in mind—seems in part to be the result of the view that the term *synonymity* ought to be used in such a way that intentionally heteromorphic expressions cannot be synonymous. It seems that they believe or assume that such a proposal, if fol-

lowed, would lead to a usage in substantial agreement with usage in general or in the texts written by linguists, logicians, and philosophers.

In the material gathered by questionnaires there are a number of answers symptomatic of that trend. Many expressions can be viewed as complexes consisting of simple or atomic expressions. If subjects are confronted with texts in which both the complex and the atomic expressions occur, they show a strong tendency to judge the complex to be questionnaire-heteronymous with the atomic, regardless of all other relations between the expressions.

This tendency has been studied by means of the questionnaires Qs1–Qs5. It has been found, for example, that “in the year 1920” is sometimes judged to be questionnaire-heteronymous with “in the year A.D. 1920” even in texts in which only happenings in the twentieth century are discussed. Even in a context with explicit, obvious references to Oslo, “at the University” is sometimes judged to be heteronymous with “at the University of Oslo.”

The arguments offered in these and similar cases are mainly of the following kind: the expression xyz is heteronymous with the expression xy because z has a meaning and it occurs in xyz but not in xy . This argument is used in spite of the circumstance that the subject interpreted the text in which xy occurred in no way different from that in which xyz occurred.

On the other hand, there are rather marked tendencies in usage (including that of linguists) of such a kind that requirements of sameness of intentional structure (including the case of intentional isomorphism) are far too strong. The widespread tendency to answer affirmatively to questions as if “is true,” “is the case,” and “is perfectly certain” were synonymous, is symptomatic of less rigorous requirements.⁵ I cannot see why future research should be better served by making a monopoly of the use of the term *synonymy* in such a way that one trend of usage, the one roughly in the direction of sameness of intentional structure, is taken as the best or most convenient. Moreover, whatever the direction in which the term is made more explicit, any concept of synonymy should be constructed with careful reference to research techniques that have already been tested in studies of natural languages.

The term *isomorphical N-synonymy* is proposed as a concept that, so to speak, lies between the concepts adapted to formalized languages with sys-

tems of explicit rules and the concepts concerned with the delimitation of kinds of usages:

Let a and b be two sentences, and let the analysis of them down to the smallest meaningful parts (according to a given system of classification) be such that they can be written:

$$1^a \cdot 2^a \cdot \dots \cdot m^a$$

and

$$1^b \cdot 2^b \cdot \dots \cdot n^b$$

1. "The sentences a and b are 'isomorphically N-synonymous'" shall mean the same as $m=n$, and there is a set of k rules, $R_1 \dots R_i \dots R_k$, by means of which it is stated that for all i , i_a shall mean the same as i_b within the field of application M , and there is no rule stating anything logically inconsistent with this set of rules.

Let us suppose that each of the rules $R_1 \dots R_k$ as well as a and b are used at least once and that no violation of the rules has occurred. If the rules are followed, i_a means the same as i_b in use; but what does that mean? In order to obtain a concept of isomorphical N-synonymity that allows subsumption and that is related to procedures already existing, a modification of (1) shall be proposed:

Let " i_a shall mean the same as i_b " be changed to " i_a shall be used in such a way that i_a and i_b are Qs1-synonymous for the users." Let (1), thus modified, be referred to as (2).

Now, the existence of explicit, semantical rules for the vernacular that hold without exceptions is doubtful, and, in any case, such rules are rare.⁶ A concept that made no reference to rules might be more useful.

3. "The sentences a and b are isomorphically Qs1-synonymous for the person P in the class of situations S " shall mean the same as "the pairs of the smallest corresponding parts of a and b that P considers meaningful are for P in S Qs1-synonymous, and so are a and b ."

S can be interpreted narrowly as a class of verbal contexts or more widely as a class of situations in which a or b or parts of them occur.

By means of this concept of isomorphical Qs1-synonymy, we may now, returning to our previous discussion, say that there is a certain percentage of people for whom no pair of sentences are Qs1A-synonymous⁷ that are not also isomorphically Qs1A-synonymous. Or, tentatively, the stronger assertion may be made that for a certain percentage of people two sentences are Qs1A-synonymous if and only if they are isomorphically Qs1A-synonymous.

The goal of formulating criteria by means of which “ 2^{10} is less than 1,000” is distinguished from “1,024 is less than 1,000” can be attained by a questionnaire; let us call it Qs22. It may roughly be said to be concerned with the operations that are performed in order to verify the truth of a statement. To the extent that the smallest meaningful parts of two statements have differences corresponding to differences in operation, one may expect that Qs22, or questionnaires of a similar kind, can bring the differences to light. Qs22 contains three questions:

1. How would you go about showing or proving that T is true?
2. How would you go about showing or proving that U is true?
3. Is there any part—including the smallest details—of the first procedure that would have to be different from the second?

If the respondent points out a difference, T and U will be said to be Qs22-heteronymous. If the answer is negative, it will be taken as a confirmation that T and U are Qs22-synonymous.

In the case of “ $2^{10} < 1,000$ ” and “ $1,024 < 1,000$,” most people would, I tentatively assert, answer (3) affirmatively—saying, for example, that the behavior involved with “ $2^{10} < 1000$ ” includes multiplying $2 \times 2 \times 2 \dots$, or consulting a table of powers, whereas the second procedure would not include this.

In general, any application of different semantical rules would result in Qs22-heteronymy.

It is hoped that this article throws some light on the relationship between conceptual constructions and empirical research in general, and questionnaire procedures in particular. It cannot be overemphasized that

EMPIRICAL SEMANTICS AND 'TRUTH'

conceptual construction must have some basis in empirical observation and that more research is needed to develop further the relationships between technical concepts such as that of intentional isomorphism or interchangeability *salva veritate* and the empirical phenomena for which they are formulated in the last analysis.

The Empirical Semantics of Key Terms, Phrases, and Sentences: Empirical Semantics Applied to Nonprofessional Language

Characterization of Empirical Semantics Through Contrasts

In what follows I will not discuss every sort of empirical semantics, but a kind or trend that has been given the proper name Empirical Semantics and has mainly flourished in Scandinavia. Its characteristics are most easily grasped by contrasting it with other trends.

For example, consider the increase of status of particulars since the start (about 1962) of the international ecological movement. We now find (1) study of the *particular* habits of *particular* insects; (2) study of the effects of putting 100 new chemicals into the environment through the study of the astronomical number of particular effects resulting from the combined action and interaction of 2, 3, 4, . . . 100 of those chemicals.

In contrast to the logical empiricism of the mid-1930s, Empirical Semantics stresses the requirement of testability of every direct and implied hypothesis about the actual use of terms, phrases, or sentences. For example, Alfred Tarski's work on truth included assertions about the agreement of his truth definition or construction with the ordinary or common use of the term. The testability of those assertions was low, however, and there was no agreed-upon methodology for testing them. The assessment of credibility was left to a kind of intuition believed to be more or less infallible among persons speaking the language. Logical empiricists, except Otto

This article was reprinted with permission from *Philosophy and Grammar. Papers on the Occasion of the Quincentennial of Uppsala University*, edited by Stig Kanger and Sven Öhman (Dordrecht, Netherlands: D. Reidel/Kluwer Academic Publishers, 1981), 135–54.

Neurath, accepted Tarski's assertions about the use of *true* and *truth*, and of many other terms, without questioning them. In this they were of course not alone, but it contrasted with their high-level requirement of testability and derivability in the natural sciences, primarily in physics. Their methodology had a kind of blind spot in the matter of actual use of terms. Empirical Semantics stepped in and offered to clarify the limits of the adequacy of the Tarski definition, using testable methods.

Karl Popper, and later Paul Feyerabend and others trained by Popper, was here in agreement with logical empiricists, although he tended to avoid semantical hypotheses. Popper certainly relied upon them indirectly, for example, in assertions about induction. If this term is not used in ways that represent only a subclass of the usages of the term, the thesis that good scientists never apply induction falls to the ground. The same holds for what he says about metaphysics.

In the late 1930s, logical empiricists cooperated with Charles W. Morris and introduced the triad syntactical, semantical, and pragmatic questions in dealing with language. In pragmatics the approach was called empirical, but it lacked a research methodology. Empirical assertion of grave importance in syntactical and semantical work was still left unsupported and relied upon an implicit appeal to intuition. Such appeals are of course unavoidable in more than 99 percent of our discussions, but are of little weight when we face disagreements about usage that affect the arguments for or against a thesis of interest.

Belief in intuition corroborated by highly sophisticated arguments also characterized the Ordinary Language movement. John L. Austin, Norman Malcolm, and Herman Tønnessen argued about the grammatical principle "no modification without aberration," concentrating on phrases like "I yawned voluntarily (or deliberately)," which Austin held to be "impossible" under certain circumstances. Tønnessen maintained a "principle of tolerance" based on empirical semantical investigations. Tønnessen contended that the intuitions of Austin concerning adverbs were deductions from old-fashioned grammar. He confirmed his own views through comparison with yawning students, of which he found a great number in university reading rooms. When Feyerabend states (1976: 381) that for "years Imre Lakatos and I were alone in our attempt to inject a little life, some personal note into philosophical debate," he forgets Tønnessen.

The highly intelligent and sophisticated assertions of Strawson about the performative function of sentences like “It is true” can be tested only in concrete life situations. It is my contention that if we as researchers in such situations asked ordinary people about the purpose or meaning or job of such a sentence, they would in much less clever, but clearer, phrases outline different performative and nonperformative functions. Lacking doctrinal prejudices, they would avoid many pitfalls.

This example brings me to a second main tendency within Empirical Semantics: the relatively high regard for hypotheses put forth by nonprofessional philosophers concerning language.

An investigation of the use of the term *true* and related terms such as *fact* and *probable* turned in the 1930s to the question of how nonprofessional philosophers would themselves conceive the meaning and function of these words.

Philosophers have ready-made answers to both the use and the conception of the use among people outside their clan. I quote some phrases they use:

“The opinion of the man in the street on the truth-notion is . . .”

“[T]o naive people truth means . . .”

“The usual criterion of error is . . .”

“Wenn man einen Bauer fragen wollte, warum er glaube, dass . . .”

“Die sinnliche Wahrheit ist die Wahrheit des Kindes.”

“Das Volk, als solches, oder der grosse Haufen, ist an seinen Vorstellungen an die Wahrheit der Sinne gebunden.”

“Der Character des Volkes und seiner Wahrheit ist Realismus.”

“[T]he definition of the truth and falsity of beliefs is not quite as simple as common sense and McTaggart suppose.”

“If common sense had been asked to formulate what is meant by the truth of a belief, this is probably what it would have written . . .”

“Dies liegt in dem blossen Sinn der Worte wahr und falsch.”

“‘Wahr’ (in der üblichen Bedeutung) ist . . .”

“Die Wahrheit ist, wie es scheint, von allen Menschen als etwas Festes, als etwas Unveränderliches und Ewiges, angesehen.”

The quotations indicate a grave underestimation of nonphilosophers, especially in regard to the diversity of "embryonic" philosophical theories among nonprofessionals.

Asked (roughly) what is common to all that is true, people who have never read any philosophical papers or conversed with philosophers answer with formulations that have been put into more than thirty classes. Class 8 we might call the Tarski class. What is true is identified with what is the case, what is so, or its function is conceived as a mere repetition of an assertion. The most frequent kind of formulation, class 10, identifies what is true with what is shown or what is proved. It might be called the verification class.

Logicians trespassing in empirical semantics have objected to the truth-verification notions, saying that "not true" is clearly not synonymous with "not verified." Nonphilosophers defend their notion by maintaining synonymy hypotheses like the following:

- (1) " p is true" syn " p is verified"
- " p is not true" syn " p is falsified"
- (2) "it is not true that p is true" syn "it is falsified that p is verified"

From (1) and (2) it does not follow that

- (3) "true" syn "verified"
- "not true" syn "not verified"

I shall not try to defend every nonphilosopher's view but only suggest that such views are closely similar to a variety of professional views. The consistency of the nonphilosophers' views and terminologies tends to be underrated.

Philosophers mostly think that "agreement with reality" is the commonsense conception. Formulations that include references to reality, real things, and similar ideas are put in class 1 in the above-mentioned systems; such formulations represent the fifth most frequent way of answering the question.

The nonprofessionals' formulations describing criteria or giving defini-

tions of “what is true” may, of course, be classified in many ways. Above I have referred to a class 1. In the same classification, formulations are put into:

Group 4: if truth is identified (in various senses) with a relation of correspondence with facts or actual things.

Group 7: if truth is identified with facts or real things.

Group 8: if truth is identified with what is the case, what is so, what is as one says; or when a function of mere affirmation is described. Compare the answers of person *B* to the utterance of *A*: *A*—It is raining, *B*—(1) Yes, it is raining, (2) It is raining, (3) That is so, (4) Yes (the “Tarski group”).

Group 9: if what is true is identified with something fixed and determined by man himself (“Truth as Convention”).

Group 11: if what is true is identified with what cannot be challenged, disproved, contradicted, or discussed or with what is indisputable.

Group 12: if what is true is identified with what is unchangeable or what cannot be otherwise. Central notion: changelessness (the “Parmenides group”).

Group 13: if what is true is identified with the relation of agreement or correspondence between something and *observation*.

Group 14: if what is true is identified with something unmistakable, with something that *cannot be mistaken* (the “Incorrigibility group”).

Group 15: if what is true is identified with that which cannot be *doubted* or with what is not actually doubted by anyone (the “Cartesian group”).

Sometimes the formulations are put forth with a low degree of definiteness of intention, but occasionally further conversation reveals astonishing consistency.

Empirical investigations suggest that *a large variety of philosophical outlooks* are alive among nonprofessionals in a potential, implicit, or “embryonic” form. One-sided education in colleges and universities perhaps reduces this diversity and works toward gray uniformity or excessive reliance upon the experts of the day.

Let me add some words to the characterization of Empirical Semantics through contrasts.

Empirical Semantics is heavily influenced by Bronislaw Malinowski and the linguists who since the late nineteenth century have fought the "intellectualist" conception of language as expression of thought. In the supplement to Ogden and Richards's provocative work *The Meaning of Meaning*, Malinowski pointed to basic functions of language in situations of fishing, hunting, and other relations studied by social anthropology—and now, also by modern etiology. Malinowski's conception and methodology contrasted markedly with the model of language as a calculus or as a set of rules for true/false assessments, and with the early Wittgenstein. In Vienna, Karl Bühler was active in propagating a much broader and more empirical-minded view of language. When the later Wittgenstein proposed a more empirical and etiological view, this was greeted in circles of Empirical Semantics with sincere appreciation, but it did not seem to convey more or clearer information than the old social anthropology of language. The tumultuous applause accorded to Wittgenstein's nonintellectual view of language seems to have had as a necessary condition the insularity of Anglo-American philosophical centers in matters of social science.

In the 1940s social science was able to sweep into European and Anglo-American universities on a grand scale. A highly critical, if not contemptuous, attitude toward the newcomer prevailed in philosophical environments, however. Logical empiricists tended to talk about social scientists, including psychologists, as hardworking, not-too-sharp fellows who did not really know what they were doing. With some patience this could, however, be shown them through logical analysis of the sentences they produced.

At the very bottom of the social science methodological status ladder we find the questionnaire, perhaps best known among philosophers from semicommercial undertakings and Gallup surveys.

From the very beginning, questionnaires have been extensively used in Empirical Semantics. Their usefulness or even unavoidableness is rather obvious if uses of a sentence among a large group of users are to be tested in an interpersonally satisfactory way.

For example, in a small room with a globe near the subject, he or she will very often use the sentence "The Earth is round" if asked to give an example of something true. The example is convenient for introducing questions about the certainty that the Earth is round, possibilities of errors,

questions of preciseness when compared to formulations in terms of a mathematical sphere and of more complex forms. In more or less “open interviews,” a “common characteristic of truth” question could then be introduced under standardized conditions. Nonstandardized conditions involve too many variables.

Rules or Habits

The kind of research programs that in the 1940s got the label Empirical Semantics (ES) must be understood as in part a strong reaction against uncritical applications of the conception of a language as a system of rules. De Saussure’s distinction between *parole* and *langue* (speech and language) is fruitful to a point but can be overdone. ES also reacted against the position that many of the classical problems of philosophy could be clarified—or even solved—by transforming them from ontological and epistemological questions to questions of language and of choice of sets of rules.

The limited force of rules may be understood from the fact that no set of rules, however comprehensive and however precise, can unambiguously determine relevant behavior patterns of an action. This holds, for example, for an action of the kind called “testing the hypothesis *H* through method *M*.” What is indicated through rules is primarily traits of behavior that *seem to be in need of being indicated*, given certain habits or mores of the community *at the time of* making the rule and in its social and physical context. Whether we do research or fish with the help of big nets, and try to describe our doings, there always *remain* relevant undescribed traits. The “outsider,” if sufficiently distant culturally, cannot use the description, whatever the quality of the translation.

Main Fields of Research in Empirical Semantics

The ES investigations have centered upon a fairly small number of topics:

1. *Occurrence analysis*. Description of function or connotations of certain key terms based on analysis of large numbers of occurrences of the terms in definite texts. There are several sorts of occurrence analysis.

2. *Metaoccurrence Analysis*. (a) Synchronic description of definitions and other metaoccurrences and their relation to occurrences. Among other data, 500 definitions of *truth* by nonprofessional and scores of definitions by professional philosophers were analyzed. (b) Metaoccurrence analysis as part of historical research. For example, metaoccurrences of *democracy* from the French to the Russian revolutions.
3. *Agreement and disagreement analysis*. For example, assessment of the scope and function of pseudoagreement and pseudodisagreement in scientific argumentations and ideological disputes.
4. *Definiteness of intention analysis*. The definiteness of intended meaning is always limited, or, in other terms, the net of discriminations relative to things (not constructs, like π) has a limited finiteness. There are ways to discover the limits, assess their function, and, if desirable for certain purposes, increase the definiteness or depth of intention.
5. *Synonymity*, or more generally, the equivalence and analyticity analysis. Elaboration of tests of criteria of close similarity of meaning or, more generally, of function. Estimation of degree of analyticity in communication. Whereas there may be doubt about certain analyticity concepts, the fruitfulness of the empirical kind has already been confirmed.
6. Contributions to theory of communication and to the development of educational instruments favoring more effective cognitive communication. These contributions furnish the conceptual framework of the above-mentioned researches.

Closely connected with ES are the efforts to elicit "embryonic" philosophies of truth and related topics among nonphilosophers, and of logical calculi like propositional calculi, and of probability. As a curiosity it may be mentioned that the frequencies of unlikely series—for example, getting six heads when tossing a coin six times—are markedly underrated if we permit ourselves to accept the internationally established statistics as correct. Such statistics have been extensively verified, but established propositional calculus should *not* be taken as an absolute. Here I disagree with Piaget, who in his experiments and interpretations takes established logic and physics at face value.

Synonymy, Operations, and Operationism

Pseudoagreement Analysis

The synonymy research within ES places a heavy stress on operational definitions, as part of the requirements of interpersonal testability, but emphatically rejects operationism (à la Bridgman or in modern forms). The rejection is a clear consequence of the semantics of preciseness and the rejection of “correct meaning.” With “intelligence” as a T_0 , one may expect an indefinite multiplicity of plausible synonymic alternatives of differing orders of preciseness. To choose one and act as if it were the only one is a form of linguistic corruption. Furthermore, fruitful operational definitions are mostly transintentional, or they are technifications rather than precizations. The designation *definition* is misleading.

The positive attitude toward interpersonal, explicitly described operations and the negative attitude toward operationism are part of a general attitude within epistemology or semantics: that of unending, expanding research rather than of science. At no point are there decisive conclusions. Research programs are closed for practical, not cognitive, reasons.

For example, agreement and disagreement are never free of a possible mixture of pseudoagreement and pseudodisagreement. The research on, say, agreement on definitions or precizations of the term *democracy* is in ES steered in such a way that no tests are taken to be conclusive. There are only instances of confirmations and disconfirmations, the weight of which cannot be exactly assessed.

The conceptual framework of ES is simple in the essentials:

Basic predicate:

(1) Syn (xyz, tuv)

“ x is synonymous for y in situation z with t for u in v .”

x is said to be a synonymic alternative (more loosely: “interpretation”) of t , and t of x .

Situations are in (1) considered to be singular, dated situations.

Three special cases of (1):

(2) $(y)(u) \text{ Syn } (xyz, tuv)$

"for all persons is x situation z synonymous with t in situation v ."

(3) $(z)(v) \text{ Syn } (xyz, tuv)$

"in all situations is x for y synonymous with t for u ."

(4) $\text{Syn } (xyz, tuv)$

" x for y in z is synonymous with t for y in v ."

Synonymity is not defined, but a variety of operational definitions or technifications are introduced, such as substitutability of x with t .

On the basis of synonymity, a number of other concepts are introduced: precisization, definition, pseudoagreement and pseudodisagreement, analyticity, biased interpretation, popularization, . . .

Precisization is contrasted with specification and elaboration.

Experiment on Definiteness of Intention

One may struggle to find suitable words for a thought or feeling, but one may also struggle to find out what was meant by an utterance. The utterance may have had the form of an assertion, or it may belong to an accepted hypothesis within a science, but this does not solve the problem of what a particular person in a particular situation intended to express by the assertive sentence, or what it conveyed to listeners.

To investigate the latter, empirical semanticists performed certain experiments. I shall give one example: The experimenter announced a lecture to an association of students of physics, and about 250 gathered in an auditorium. After talking for about twenty minutes, the lecturer said "The Earth is surrounded by a gravitational field" in a rather natural context and without particular stress. This was a signal to a mob of assistants to invade the gathering with copies of a questionnaire, which were handed to the students. The basic questions read, "How do you interpret the utterance 'The Earth is surrounded by a gravitational field'?" "Do any of the following sentences convey to you what the utterance conveyed to you?"

Two classes of answers are of particular interest, the “I do not know” answers and the “no discrimination” answers. They reveal the limits of the definiteness of interpretation among hearers.

Are Alfred Tarski's Empirical Hypotheses Testable?

The clash of opinions on language was clearly evident behind the scenes at the Third Congress for Unified Science in the Salle Descartes at the Sorbonne. What was Tarski really trying to do in his masterly dissertation on truth? Generally, it was thus conceived:

The task which Tarski sets for himself is that of finding a materially adequate and formally correct definition of truth. The requirement of material adequacy is *simply* the requirement that the definition, once achieved, shall correspond more or less closely with that concept of truth which all of us have in mind before we ever undertake the task of explication.

(Linsky 1952: 3; my italics)

Tarski's important theory on truth, rescuing the objective or absolute concept of truth from relativism and subjectivism, was at the congress to be defended and duly hailed by Karl Popper.

I had a discussion note in which I maintained the following theses (here given in abbreviated form):

1. Tarski's theory contains empirical hypotheses, namely, statements about ordinary language (*die Umgangssprache*).
2. The statements are vague and ambiguous and not directly testable by research.
3. Testability implies operationalization: the finding and communication of procedures that can corroborate the modified hypotheses.
4. Preliminary tests by simple social science techniques involving questionnaires and occurrence analysis suggest that the adequacy of the Tarski analysis is very limited.
5. The extremely high level of preciseness and logical rigor in the formal development in Tarski's work contrasts dramatically with the sloppiness of the statements about ordinary language.
6. Any movement using the epithet *empirical* as a positive key term

should instigate empirical research in case this is necessary to confirm or disconfirm basic theories.

7. The term *true* is central in various fields of philosophy, and the suppression of certain directions of precization (that is, a subgroup of concepts) impairs or stultifies our minds. The claim that one concept is adequate favors dogmatism.

In meetings before the opening of the session, Carnap contended that the empirical material and the inferences drawn from it would cause confusion, not clarification. Neurath's objections should suffice, and as they were well discussed beforehand, the plenum discussion would be fruitful and orderly. I agreed, having the feeling that nobody would think it even meaningful to do empirical *research* on ordinary language.

According to Tarski and those following him, the *Umgangssprache* permits unlimited (*unbeschränkt*) use of the concept of truth. Propositions that negate themselves are permitted.

Such a hypothesis is empirical and we must ask, How is it testable? By what procedures? How is the metaphor of "permittance" eliminated? How are the rules of the *Umgangssprache* found?

The weight of the criticism of Tarski's hypothesis is not that it is false, but that it is not made operational and therefore not tested.

A kind of test was made in 1936 and the result was negative.¹ It made use of open questionnaires related to the antinomy of the liar. The persons speaking the *Umgangssprache* did not interpret any sentences in such a way that they negated themselves. The existence of a *rule* of the *Umgangssprache* that permits it was not in evidence, nor a *rule* that prohibits it. Rules may be *invented* that approximately picture the complex regularities of ordinary usage. In that case, there will be no rule of unlimited use of *true*.

Analytic/Synthetic

A kind of analytic/synthetic distinction is introduced in ES, but not as an absolute distinction. The point of view of ES toward the debate on analytic/synthetic is best formulated in Tore Nordenstam's eminently clear dissertation, *Empiricism and the Analytic-Synthetic Distinction* (1972).

Ludvig Løvestad (1945a,b), using ES procedures, concluded in 1945

that the analytic/synthetic distinction plays little or no role in natural science, and explained why. His work is little known, however.

The procedure requires (1) splitting sentences into parts, and (2) introducing rules in relation to which sentences may be analytic or fall into a broader category of “analytoform.” A sentence is analytoform if, for at least one plausible interpretation (synonymic alternative), it is analytic.

A hypothesis that a sentence is analytic is confirmed only if it can be shown that it occurs within the context in which the rule is intended to be valid and only in relation to that rule. There may be a number of other rules (as in the case, for example, of the chemistry of acids) intended to cover the same or part of the same context. The same sentence may be nonanalytic in relation to all rules except one. In most cases, the task of interpretation of the rule formulation will not furnish any simple, definite conclusion because of ambiguity and vagueness.

So much about the role of rules.

Translations

Under what condition would the sentence U be a *perfect translation* of the sentence T ? The hunt for an eternally perfect translation for all people in all situations is rather pointless. As a point of departure we should, according to ES, take particular acts of communication and ask for synonymy:

$$(1) \text{Syn}(Up_1s_1; Tp_2s_2)$$

when, for example, s_1 is not a singular dated situation but a *kind* of situation—let us say, when the speakers are using an implement for fishing (à la Malinowski). The persons p_1 and p_2 may be considered to cooperate, in spite of having different mother tongues. Suppose after a time they use T or U as completely interchangeable in communication with each other *during fishing*. In other situations they may make a distinction. We may introduce various tests or operational criteria of the interchangeability. On the basis of (1) the presence of two different mother tongues (U and not T belonging to one, and T and not U belonging to the other) and (2) the presence of certain kinds of synonymy operationally introduced through interpersonal tests, we may define U as a *perfect translation* for p_1 and p_2 in s_1 and vice versa.

Generalizing, we may talk of the total class of persons p_1 speaking a certain language L_1 and the total class of persons p_2 speaking L_2 . The chances of finding a perfect translation in this case, even if the kind of situation s_1 is very narrow, is, of course, very small. For most purposes translations very far from being perfect may do the job.

At this point, measures of definiteness of intention are relevant. In general, one may say that the chance of a perfect translation is: (1) inversely proportional to the degree of definiteness of intention required; (2) proportional to the narrowness of class of persons; (3) proportional to the narrowness of class of situations; and (4) inversely proportional to the distance between the two languages.

If we do not envisage a practical situation like fishing, but the translatability of an abstract text, for example, a text on democracy, occurrence analysis and metaoccurrence analysis of a number of terms are required. The uses of the Russian term usually translated into Norwegian by the word *demokrati* are obviously influenced by events in Soviet Russia since 1917. The history of Norway has been quite different. Occurrence analysis today would reveal complicated differences. On the metalevel there are also differences. They may *in part* be roughly indicated by saying that economic relations between the citizens are in the Russian terminology highly relevant in estimating the degree to which a regime is democratic, whereas in Norwegian metaoccurrences, references are mostly to elections and the structure of government in general.

In any case, meaning hypotheses in the form of assertions that term A in language L_1 has the meaning B in language L_2 can be confirmed (or disconfirmed) only to a certain degree. There will never be a single hypothesis that can cover the total class of occurrences within an interval of time. This is a situation commonly found in any empirical field of study. Moreover, there will of course be very different kinds of hypotheses in relation to the great variety of precizations of the word *meaning*. In ES that term is avoided through use of the synonymity terminology. The above introduction of a term *translation* indicated how the elimination is done in a particular case.

The above implies a thesis of "indeterminacy of translation." There are, for example, indefinitely many rules (according to occurrence analysis) that in principle cover any set of occurrences of a term or sentence. Indefinitely

many translations will all fit the occurrences. (From this, however, do not follow certain negative theorems recently formulated by D. Føllesdal.)

One persistent trait of ES is not only the equiminded acceptance of diversity of interpretations and hypotheses, but even the stress on listing diversities. The attitude is closely connected with attitudes in plant geography, social anthropology, local history, and other “soft” natural and humanist fields of research. It is very different from dominant attitudes in formal logic, mathematical physics, and other “tougher” fields. One may say that the extremely positive attitude toward diversity is in line with theorem 24 of part V of Spinoza’s *Ethics*. “The more we understand particular things the more we understand God.”

“Showing” Contradictions

This year—the tricentennial anniversary of Spinoza’s death—a great number of experts on his work will be publishing and lecturing. Very few of them seem to believe in the fruitfulness of semantical studies. To me, however, the fruitfulness of ES occurrence analysis, and especially of equivalence analysis, seems beyond doubt in Spinoza research.

There are today still a number of experts on Spinoza who think they can *show* that Spinoza’s *Ethics* contains contradictions in the sense of inconsistencies. In a recent lecture before an audience of several hundred “friends of Spinoza,” Leszek Kolakowski (1973) announced a number of contradictions, some of which he even contended he could *prove*. According to the methodology of occurrence analysis, it is impossible to *prove* such inconsistencies. Empirical working hypotheses cannot be proved. The methodological situation in this matter is no different from that in historical geology or in cosmology.

If we analyze the occurrences and metaoccurrences of basic terms of the *Ethics*—*liber* (free), *determinata* (determined), *potentia* (power), *virtus* (virtue), and others—a variety of interpretations are open. This holds even if we add information from other texts of Spinoza, and from authors with, in part, similar terminology (for example, Descartes). I shall later concentrate on one source of differences of interpretation, the expressions of equivalence.

If we have a pair of sentences T_0 and U_0 that by superficial reading seem inconsistent, we might take this as a sufficient condition of inconsis-

tency: that for all pairs of plausible precizations beyond a certain level of preciseness, the pairs are instances of logical inconsistency. The judgment of plausibility is, however, highly speculative. There is no room for proofs in a rigorous or even a sloppy sense; there is only room for working hypotheses of limited testability. I say *working* hypotheses, because the assessment of plausibility of interpretation depends on other sentences of the text that contain terms intimately connected with the terms found in T_0 and U_0 . Thus, research must proceed from a rather narrow set of terms or sentences to a very wide one. The sentences of the *Ethics* hang together—that we all agree on.

The diversity of interpretations that fit the given class of occurrences of certain terms or sentences is best conceived if we think of them as interpretative rules. Using the broad theorem of Mach-Duhem-Poincaré in general methodology, we may say that there are indefinitely many different rules of grammar and dictionary consistent with a given set of occurrences of a term or sentence. Let me mention a central term of Spinoza's *Ethics*: *liber*, free.

There is a famous absolutistic metaoccurrence of *res libera* (free thing) in part I of the *Ethics*. A "free thing" is by definition synonymous with "a thing that exists solely out of the necessity of its own nature, and is determined to act solely out of itself."

Every plausible interpretation of Spinoza's text at this point requires that we exclude human beings from the class of free things. Only one so-called thing is free, God, substance, or Nature. Nevertheless, Spinoza talks sometimes of the free human being, *homo liber*. If we accept the hypothesis that *liber* here is used in the same way as announced in his definition, we may infer not only that there is no *homo liber* but that the expression as it occurs in the *Ethics* involves a contradiction on the same shameless level as the famous "square circle."

This conclusion leads to difficulties, however. According to the note on theorem 54 in part IV, to live according to reason is to be free (*ex ductu rationis vivant, hoc est, ut liberi sint*). The free human being seems to be, in part IV, a being not determined to act solely out of itself, but to a high degree out of itself or from its own nature, or self-caused. Thus, Spinoza does not here exclude the possibility of free human beings.

It cannot of course be proved, but a rather good hypothesis is the one

that postulates an absolutistic and a nonabsolutistic use of *free* in Spinoza's texts. In other words, the term *free* is used in at least two senses. The absolutistic metaformulation might then be interpreted as synonymous with the more precise sentence "I am going to say (*dicetur*) that that thing is *absolutely* free, which exists *solely* out of the necessity of its own nature. . . ."

The talk about free human beings in the later parts of the *Ethics* will then naturally be interpreted in a nonabsolute sense of 'free'. This approach is quite successful, I think. It results in elimination of the threatening inconsistency when the metaoccurrence in part I is taken to cover all occurrences of *free*. Every alleged inconsistency proclaimed by Kolakowski (1973) and by a number of other distinguished scholars can be eliminated in the same way. (This is strictly a working hypothesis.)

Every sentence announcing what *will be* said, using *futurum simplex*, implies, if the definiteness of intention is taken to be fairly high, an announcement of the range of intended validity. The *Ethics* consisted originally only of the first part, and the absolutistic use is confined to that. Consequently, we consider the intended range of validity to be limited to part I.

Some experts think that Spinoza's *system* requires the absolute sense, but there is no way of getting to one single system as being that of Spinoza. What we can do is introduce reconstructions, more or less freely. Personally, I am for reconstructions that permit me to talk about human beings being able to obtain higher levels of freedom, that is, being able to *increase* their level of freedom. This means that I prefer reconstructions such that the term *free* is not used exclusively in an absolute sense.

In any case, neither the so-called determinism nor any other doctrine of the *Ethics* can be *shown* to contain inconsistencies. The methodology of occurrence analysis rules it out. A different methodology might be adopted, and in relation to that inconsistencies might be shown or even proved. No such methodology has been formulated by Spinoza experts, however.

Of more interest are attempts to interpret the *Ethics* in such a way that it becomes consistent from the point of view of formal logic. Professor J. Friedman has, in a not-yet-published dissertation, concluded that the proofs of part I of the *Ethics* obtain a consistent and valid form if 164 premises are added. This seems a somewhat large number, but all except about twenty are of a very innocent kind. The work is of interest for all who would wish to learn from Spinoza in a positive way.

Expressions of Extensional Equivalence

Nearness of cognitive meaning or function has always been a favorite theme of Empirical Semantics. A number of expressions in the *Ethics* suggest at least a kind of extensional or referential identity or near identity, in short, extensional equivalence with certain other expressions. Some pairs may be intensionally equivalent, but considering the nominalistic inclination of Spinoza, and also the difficulty of testing hypotheses of intension, I shall limit myself to extension.

Here are some of the expressions that consist of more than one word:

by <i>x</i> I understand <i>y</i>	<i>per . . . intelligo . . .</i>
by <i>x</i> we understand <i>y</i>	<i>per . . . intelligimus . . .</i>
to understand the same by <i>x</i> and <i>y</i>	<i>per . . . et . . . idem intelligere</i>
<i>x</i> does not mean anything else than <i>y</i>	<i>. . . nihil aliud significat quam</i>
<i>x</i> and <i>y</i> are one and the same	<i>. . . unum et idem sunt</i>
<i>x</i> is nothing else than <i>y</i>	<i>. . . nihil praeter . . . est</i>
<i>x</i> or (which is the same) <i>y</i>	<i>. . . vel (quod idem est) . . .</i>

Some of the others, consisting of only one or two words, are very common. The most common one is "*x* or *y*," *x sive y* (for example, "God or Nature," *Deus sive Natura*). Other very common ones are "*x* or *y*" (*x seu y*) and "*x*, that is, *y*" (*x, hoc est, y*).

In all, there are about 250 occurrences of expressions of extensional equivalence (see figure 1). Their exact interpretation is in most or all cases open to different views. The resulting differences in interpretation of the system of Spinoza are substantial, especially since most of the fundamental terms of the system occur in equivalences.

For example, the terms *power* and *virtue* are connected with several strong terms of equivalence. There is also an equivalence between *virtue* and *love of God*. It is said in the proof of theorem 42 in part V that love of God (*amor erga Deum*) is virtue itself (*ipsa virtus est*). Now, if in the *Ethics* we put the term *virtue* wherever we find *power*, we get a text that sounds very Christian and very tender-minded in the sense of William James. If, on the other hand, we substitute *power* everywhere for *virtue*, we get a text sounding of Machiavelli or Thomas Hobbes, and very tough-minded in the sense of William James.

Spinoza is said to be a *Gottbetrunkenener Mensch*. This characterization

Figure 1. Strings of equivalence: an example. *Number references:* 53—Part III, Prop. 7z, Demonstratio; 59—Part III, Prop. 9, Scholium; 71—Part III, Prop. 55, Scholium; 72—Part III, Prop. 55, Cor. 2, Dem.; 91—Part IV, Def. 8; 120—Part IV, Prop. 33, Dem.; 122—Part IV, Prop. 52, Dem.; 150—Part IV, App. 3; 174—Part 5, Prop. 4, Scholium; 240—Part V, Prop. 41, Dem.; 241—Part V, Prop. 42, Dem. (Numbers refer to lists of equivalences in Naess 1976.)

would be still more to the point if, where he writes *virtue*, we placed *love of God* instead. Since we have two famous equivalences of God and Nature (*Deus sive Natura*), however, we could make a second choice and write Nature wherever he has *God*. He then suddenly changes from *ein Gottbetrunkenener* to *ein Naturbetrunkenener*, a kind of nature mystic.²

The semantical point to be made is that reconstructions must introduce a term or a complex expression that fits both *potentia* and *virtus*. Clearly, neither the term *power* nor the term *virtue* can do the job. Or one might define completely new terms, for example, *potus* or *virtia*, analogous to Eddington's invitation to use *waveicle* as a term in physics for an entity that has specific properties of both waves and particles.

The important lesson is that the equivalences found in the *Ethics* rule out some interpretations of the basic terms as very implausible, but they leave room for a number of very different others.

Basing our concept of interpretation upon the kind of concepts of synonymy starting on page 67, we may confidently predict that there will not be any convergence of interpretations of Spinoza's text with increased

EMPIRICAL SEMANTICS AND 'TRUTH'

research. It is perhaps more realistic to put forth general interpretations of his system, or parts of it, as *reconstructions*. Sender/receiver preciseness depends upon using terms understandable today. This implies "translating" Spinoza in a way that makes manifest the many more or less doubtful auxiliary hypotheses necessary to fabricate the translation.

Empirical Semantics, and especially occurrence analysis of meta- and use occurrence, may be of some use in the clarification and validation of such hypotheses.

Typology of Questionnaires Adapted to the Study of Expressions with Closely Related Meanings

If carried out with an eager and open mind, painstaking empirical research leads us into vast uncharted regions of facts and relations. The more we penetrate the depths of such regions, the more we are fascinated. We are—often against our will—drawn farther and farther into the study of details and intricate structures revealed by the data found or collected. Bystanders are often astonished by this: what has gradually broadened into a whole world, is, seen from outside, only a secondary and special field or at least a field of no importance for any great problems—and the outsider is right; it is only rarely that a piece of empirical research obtains a great weight in solving or clarifying central problems.

Much that is being done, especially in the methodologically less advanced areas of science, is not very interesting or attractive except to a few people working in exactly the same areas. This holds good of some studies carried out by Socratic interviews or by (standardized) questionnaires intended to reveal more and more about the relations between words of closely related (cognitive) meaning. It is my contention, however, that in spite of the, in many ways appalling, crudity of the questionnaire techniques and in spite of the manifest inability of many subjects to enter into difficult linguistic or other fields, the data gathered are often apt to reveal or suggest as much to the researcher as do penetrating meditations or introspections based on data found in one's own head or gathered in an informal way. Primarily, though, it is the very richness of the materials, the surprising differ-

This article was reprinted with permission from *Logic and Language: Studies Dedicated to Professor Rudolf Carnap on the Occasion of His Seventieth Birthday*, edited by B. H. Kazemier and D. I. Vuysje (Dordrecht, Netherlands: Kluwer Academic Publishers, Synthese Library, 1962), 206–19.

ences among "ordinary people" (nonphilosophers and nonlinguists) in how they conceive terms, phrases, texts, and functions of language—together with uniformities at places one could not have foretold—that spur one to renewed efforts.

In this article, I shall try to give a condensed survey of most kinds of questionnaires used in my studies of synonymy and of some kinds used by other authors (Revie, L. Lövestad, H. Tønnessen). The list forming the main part of this article will, I hope, facilitate the work of other researchers who wish to contribute to empirical semantics. There is much confusion about how questionnaires can be used and an underestimation of the variety of approaches or techniques.

In particular, there are three old misconceptions to be fought: (1) If one wishes to know how a person uses a term, the questionnaire method consists in asking the person directly how he uses it. (2) If the formulations of the questionnaire are misinterpreted, there is nothing one can do with it to find out how and why. (3) When a researcher asks a subject a set of questions, this set is identical with the questions the researcher asks himself in his research program.

Questionnaire is in this paper taken in a wide sense: a set of formulations of questions in a definite order that are intended to be placed before an identified group of people under conditions—verbal and nonverbal—that are to some extent known or tested or standardized. It is a research instrument that is adapted to the need of asking more than one person the same questions one or more times under various conditions.

If controversial questions are asked, this does not imply that the researcher believes he can get the correct answer by using questionnaires containing just those questions. Very often, the researcher is interested primarily in questions that are not put into the questionnaire. Thus, only a minority of my questionnaires pose direct questions to the subjects such as "Do *T* and *U* express the same meaning to you in this context?" and if direct questions are asked, the answers are not taken at face value. The material obtained may furnish evidence in an indirect way; it may strengthen or weaken an argument that is relevant (but scarcely decisive) for the questionnaire. Last, but not least, there is nothing in the technique of questionnaires that precludes including competent people as subjects. Professionals and experts do, however, tend to refuse to answer isolated questions and in-

sist upon reformulating, modifying, and expanding the formulations of the questionnaire in a way that makes *comparison* with other respondents difficult. This is not an obstacle of major importance, but it certainly makes it unwise to use professionals as subjects except when they are valuable for the specific aim that has led the researcher to frame the questionnaire.

The following classificatory system suggested itself as the number of synonymy questionnaires that I developed in the course of research increased and it began to be difficult to survey their similarities and differences. It is reasonable to expect that other classifications will become more convenient or theoretically more important at later stages of research.

In studying closeness in meaning by means of questionnaires, it has been one of my aims to develop at least one kind of questionnaire corresponding to each kind of well-known philological and philosophical criterion or definition of (cognitive) synonymy. One might have expected that this aim would result in questionnaires with “crucial” questions reminiscent of the formulations used in those criteria or definitions. The indirect character of most (good) questionnaires and the nonoperational character of the criteria or definitions make the relation between professional definitions rather intricate, however.

An example will illustrate this. Carnap introduces a concept *intentional isomorphism* that may be said to express a kind of strong relation of sameness of meaning. Why is there no questionnaire directly corresponding to it, that is, a standardized set of questions including, and only including, what must be answered in order to identify a case of logical isomorphism? First, the concept of intentional isomorphism is constructed in relation to sets of semantical *rules*, not *use*. Like the concepts of *L*-implication and *L*-equivalence, it has no meaning except for formal languages. Now, questionnaires are instruments for finding out how people *use* certain expressions, not for ascertaining the formation and transformation rules of calculi (which possibly have never been used by anybody). Second, if the concept of logical isomorphism is somewhat changed so as to be relevant for investigations of use, there will not be one characteristic questionnaire corresponding to it, but a characteristic *set* of ordinary questionnaires: if two complex expressions $x_1y_1z_1$ and $x_2y_2z_2$ can be analyzed each into three components, x_1, y_1, z_1 and x_2, y_2, z_2 , the concept of logical isomorphy can be said to require synonymy not only of the pairs $x_1y_1z_1$ and $x_2y_2z_2$ but also of the three pairs of minimum expres-

sions x_1x_2 , y_1y_2 , and z_1z_2 .¹ This means that we may use questionnaires of any of the families surveyed below, but in characteristic quadruplets.

Terminology

Individual copies of questionnaires have the same status semantically as individual occurrences of sentences. There may be a vast number of copies of them. We shall think of questionnaires as written. It is important, however, to remember that when used orally, they give rise to acoustic processes, each one with its peculiarities.

Each questionnaire (Q) has a name; those used in studying synonymy (s), in a vague and broad sense of closeness in meaning, have the name Qs and two numbers, as in Qs4 No. 3. Qs4 is to be considered an abbreviation for Qss4, the second s for "statement." Questionnaires of the class Qss study likeness of meaning between statements. Closely corresponding questionnaires concerning synonymy of designation (terms) get the name Qsd4, and so forth. Similarly, the *i* in Qsi4 and the *q* in Qsq4 stand for "imperative sentence" and "question sentence," respectively.

To avoid unnecessary complications, questionnaires identical with Qs4 except for minute or peripheral modifications of wording have been called Qs4 questionnaires.

Each synonymy questionnaire concerns a pair of sentences or designations, the so-called crucial expressions the synonymy of which is to be investigated—for example, "true" and "perfectly certain." The second number in the questionnaire name changes with changing expressions to be investigated or with changing order of expressions: Qsd1 No. 11 investigates the use of "true"—"perfectly certain"; Qsd1 No. 12 investigates "perfectly certain"—"true"; Qsd1 No. 13, "the case"—"perfectly certain"; Qsd1 No. 14, "the case"—"true," and so on.

Just as in the case of sentences, their meaning and the attitude toward them change with the context; therefore, the order in which the questions are posed may affect the answer.

The name Qsd1 is (1) a class designation denoting all questionnaires that are generated by inserting definite designations into two open places in a sentence sequence. The sentence sequence is the same for each of the questionnaires; the open places are those of the crucial expressions. Qsd1 is also (2) a name for the skeletal sentence systems (sentence schemes) we get

by taking away the crucial expressions from the particular questionnaires Qsd1 No. 1, Qsd1 No. 2, etc. If nothing else is explicitly stated, Qsd2 is intended as a class designation. Broader classes are designated by such symbols as Qsxy—the class of all kinds of synonymy questionnaires, including those concerning question sentences.

Next in importance after the classification of synonymy questionnaires into those concerned with declarative sentences, imperative sentences, question sentences, and designations, we have found the classification according to the terms used in, and the meaning intended by, the questions of the questionnaire. This gives the *fundamentum divisionis* of the following classification. Five families of questionnaires are distinguished.

The first family includes all questionnaires in which the subject is asked, roughly speaking, whether two given expressions mean the same or express the same. The crucial questions include what we call *synonymy expressions*: “express the same assertion,” “mean the same,” and so on. Nearly all questionnaires of this family have asked whether a pair of expressions mean the same *for the respondent* when they occur *in a definite context* given in the questionnaire. More general questions are, of course, possible within the range of variation of the questionnaire family.

Using the terms of the questionnaires, one may say, roughly speaking, that to be taken as confirmations of synonymy in some sense, the answers must *state* that certain statements express the same or mean the same. In the classification, this requirement is named a *synonymy requirement*.

Characteristic of the first family is the close relation between crucial question and synonymy requirement. A subject is asked, for example, whether two sentences *T* and *U* express the same, and the answer yes is the only requirement for classing *T* and *U* as synonymous (for example, Qs-family-1-synonymous) for the subject relative to the contexts.² The “level of directness” of the questionnaires is maximal. They are used primarily to observe how answers undergo variation with variations of subjects and—often more important—with change of contexts.

The second family and the rest of the questionnaire families avoid “mean the same” and related expressions. They are with few exceptions more complicated and judged more difficult by the respondents. Roughly speaking, a first group of questionnaires of family 2 invites the respondent to try to conceive of variations in conditions affecting the truth-value of sentences.

The concepts of synonymy intended to be studied by these question-

naires are related to the truth-value concepts proposed by Carnap and others. The synonymy requirement is inconceivability of a difference in acceptance. A second group avoids the appeal to the imagination and thus *decreases the task character of the questionnaires*. Roughly speaking, various conditions are indicated in the questionnaire, and the respondent is invited to answer whether under those conditions the crucial sentences would be true. A third group is a plain true-false questionnaire, by which the respondent is invited to judge each sentence of a series containing the crucial expressions as to its truth-value. The synonymy requirement is that each pair of sentences, the members of which differ only in crucial expressions, has the same truth-value.

It should not be necessary to go into detail in characterizing the families 3, 4, and 5. Rough characterizations are given below.

Family 1

Use of synonymy expressions such as "synonym," "mean the same," "express the same (proposition, assertion)."

Synonymy requirement: sameness of meaning.

Associated philosophical concepts: interchangeability *salva significatione*, synonymy in intention.

Level of directness: maximum. If N. N. *says* that *T* and *U* mean the same for him, *T* and *U* mean the same for him.

Genus 1

Synonymy expression: "express the same assertion."

Synonymy requirement: expressiveness of same assertion.

Mode of presentation: invitation to imagine interchange of expressions.

Prototype: QSI (Naess 1953: 360 [SWAN I]).³

Species 1

Synonymy question related to a definite occurrence in a definite text and to a definite event of interpretation by the respondent.

Prototype: QSI (ibid.).

Species 2

Synonymity question more general than in the case of Qs1. Generalization in respect of occurrences, texts, events of interpretation.

Prototype: Qs2 (ibid., p. 364).

Species 3

Like species 2, but furnished with an introduction requiring a definite criterion of sameness of cognitive meaning to be used by the subject. (The criterion is, roughly, sameness of conceived conditions of truth.)

Prototype: Qs30 (Naess 1954a: 37).

Genus 2

Synonymity expression: “mean the same.”

Synonymity requirement: sameness of meaning.

Mode of presentation: invitation to imagine interchange of expressions.

Prototype: Qs3 (Naess 1953: 366 [SWAN I]).

Species 1

Synonymity question related to a definite occurrence in a definite text and to a definite event of interpretation by the subject.

Species 2

Same synonymity expression as for species 1, but question of a more general nature.

Prototype: Qs3 (ibid.).

Genus 3

Synonymity expression: “synonym.”

Synonymity requirement: synonymity.

Mode of presentation: subjects asked to list synonyms of a given word.

Such a questionnaire has not been used by the author, but it appears in a mimeographed doctoral thesis by Revie (University of California). It is not classed as a synonymity questionnaire “proper,” because then the phrasing of many theorems on likeness of meaning would be more complicated.

EMPIRICAL SEMANTICS AND ‘TRUTH’

Species 1

No reference to texts or persons; straightforward invitation to list synonyms.

Prototype: see dissertation by Revie.

Family 2

Synonymity requirement: nonexistence or inconceivability of a difference (of some kind) under a variety of imagined or stated conditions.

Associated philosophical concept: inconceivability of logical inequivalence.

Genus 1

Synonymity expression: “same conditions of acceptance (and rejection) of some kind.”

Synonymity requirement: inconceivability of difference in conditions of acceptance.

Mode of presentation: invitation to conceive of different conditions of acceptance.

Prototype: Qs10.

Species 1

Synonymity expression: “same conditions of acceptance”; no specification of kind of acceptance.

Synonymity questions related to a definite occurrence in a definite text.⁴

Prototype: Qs5 (Naess 1953: 368 [SWAN I]).

Species 2

Synonymity expression: same as for species 1.

Synonymity question of a more general character: texts not given, authors said to be different.

Prototype: Qs10.

Species 3

Synonymity expression: “same conditions of acceptance *as true* (versus rejection as false).”

Synonymity requirement: inconceivability of difference in conditions of acceptance *as true*.

Synonymity question related to definite occurrence in a definite text.

Prototype: Qs11.

Genus 2

Synonymity expression: no synonymity expression.

Synonymity requirement: interchangeability *salva veritate*.

Mode of presentation: invitation to answer whether certain statements are true or false. The whole questionnaire is formulated in the object-language.

Prototype: Qs29.

Family 3

Synonymity expressions: no synonymity expression, or “(same) necessary or sufficient conditions,” etc.

Synonymity requirement of (two) statements: if the first, then the second, and vice versa. Synonymity requirement of designations: if subsumability under the first, then under the second, and vice versa.

Associated philosophical concept: logical equivalence.

Genus 1

Synonymity expression: “(same) necessary, sufficient (condition) of.”

Synonymity requirement: truth (or tenability, etc.) of *a* being a necessary and sufficient condition of truth of *b*.

Mode of presentation: texts with *a* presented; subjects invited to answer pairs of questions: do you consider it a necessary (sufficient) criterion of the truth of *a* that *b*₁ is true?

Prototype: Qs4 (Naess 1953: 369 [SWAN I]).

Species 1

Synonymity expression: “necessary and sufficient criterion (condition) of the truth of.”

EMPIRICAL SEMANTICS AND ‘TRUTH’

Synonymity requirement: truth of *a* necessary and sufficient criterion of truth of *b*.

Prototype: Qs₄ (ibid.).

Species 2

Synonymity expression: same as for species 1.

Synonymity requirement: same as for species 1 plus “truth” of *b* necessary and sufficient condition of truth of *a*.

Prototype: Qs₂₀.

Species 3

Like species 1, but modified in such a way that answers are *use occurrences* (for example, a yes answer to “Do you accept that if N. N. loves his neighbor as himself, he is a good man?” rather than “Do you accept the statement ‘If N. N. . . .’”).

Mode of presentation: invitation to answer questions about the relation between the crucial expressions and each member of a list of statements $V_1, V_2, \dots V_3, \dots$. The questions have the form “Do you consider it a necessary (or: sufficient) condition of the truth of *T* (or: *U*) that V_1 is true?”

Prototype: Qs₂₅.

Genus 2

Synonymity expression: “if V_1 then (not-) *T* and if V_1 then (not-) *U*,” etc.

Synonymity requirement: for all *i* and *j*: if V_1 then *T* and if V_1 then *U*, if V_j then not *T* and if V_j then not *U*.

Prototype: Qs₆ (Naess 1953: 369 [SWAN I]).

Family 4

Argumentational synonymity. Closely related to family 3 but marks the transition from formal logic to logic of argumentation (*pro et contra dicere*).

Genus 1

Synonymity expression: none.

Synonymity requirement: (1) sameness of pro-arguments and sameness of contra-arguments; 2) same strength of pros and cons.

Mode of presentation: invitation to imagine arguments that would count as pro (or con, or be neutral) in relation to T (or U) but not in relation to U (for T).

Prototype: Qs8 (ibid., p. 374).

Genus 2

Synonymity expression: none.

Synonymity requirement: same as for genus 1.

Mode of presentation: list of statements offered as possible arguments.

Subjects invited to answer questions concerning the relation of the statements to T and U .

Family 5

Synonymity expression: none.

Synonymity requirement: sameness of extension, sameness of subsumption, sameness of class membership.

Associated philosophical concepts: synonymity concepts for extensional languages.

Genus 1

List of expressions offered.

Crucial question: "is this an example of . . . ?"

Synonymity requirement: sameness of example subsumptions.

Prototype: Qs18.

Genus 2

No initial list of expressions offered. Subjects invited to give examples.

Examples offered by subject A presented to B and those by B to A , etc.

Prototype: Qs19.

Family M

Metaquestionnaires

The aim of metaquestionnaires is to test the questionnaires already presented to a subject by studying how the subject interpreted the crucial question (etc.) of the questionnaire. (Metaquestionnaires thus defined need not be synonymy questionnaires.)

Genus 1

Mode of presentation: a subject is asked whether he would have given a different answer to a (definite) questionnaire if the crucial question had not been what it was, but one of the questions on a list presented to the subject.

Do these so-called synonymy questionnaires *really* measure or somehow indicate synonymy? The answer must be negative, because there is no such thing as synonymy as such. In philological and philosophical literature the term has been defined in various ways, and many (mostly inapplicable) formulas have been put forth as criteria of synonymy. When we reformulate the criteria in such ways that they can be applied to concrete instances of use of certain sentences or other units of speech, the answers to the questionnaires are seen to be *relevant* as material. There is, on the other hand, no criterion applicable to concrete cases of verbal communication that deserves the name of *the* criterion of synonymy in use.

In various publications Rudolf Carnap has pointed out that the analysis of synonymy in natural languages by questionnaire procedures and by other techniques outlined in my *Interpretation and Preciseness* (SWAN I) supports his "intensionalist thesis."⁵ This thesis "says that the assignment of an intension is an empirical hypothesis which, like any other hypothesis in linguistics, can be tested by observations of language behavior. On the other hand, the extensionalist thesis asserts that the assignment of an intension, on the basis of the previously determined extension, is not a question of fact but merely a matter of choice. The thesis holds that the linguist is free to choose any of those properties which fit to the given extension; he may be guided in his choice by a consideration of simplicity, but there is no question of right or wrong" (Carnap 1956: 62).

Arguing for his intensionalist thesis, Carnap (ibid., p. 63) invites the reader to suppose

that one linguist, after an investigation of Karl's speaking behavior, writes into his dictionary the following:

(1) *Pferd*, horse,

while another linguist writes:

(2) *Pferd*, horse or unicorn.

Since there are no unicorns, the two intensions ascribed to the word *Pferd* by the two linguists, although different, have the same extension. If the extensionalist thesis were right, there would be no way for empirically deciding between (1) and (2). Since the extension is the same, no response by Karl, affirmative or negative, with respect to any actual thing can make a difference between (1) and (2). But what else is there to investigate for the linguist beyond Karl's responses concerning the application of the predicate to all the cases that can be found? The answer is, he must take into account not only the actual cases, but also possible cases. The most direct way of doing this would be for the linguist to use, in the German questions directed to Karl, modal expressions corresponding to "possible case" or the like.

The texts and reference lists used in many questionnaires have just this function, to elicit verbal reactions toward objects or relations that the subjects may not have reacted to before and possibly never will react to except verbally.

The main weakness of the extensionalist thesis as formulated (and rejected) by Carnap seems to me to be an implicit assumption that empirical studies of *extensions* could end in a definite hypothesis H_0 about sameness of extension of two expressions T and U of such a kind that there would be no group of hypotheses H_1, H_2, \dots covering equally well the materials of the observational journals. However, if hypothetico-deductive methodology is applied to observations of concrete instances of use of T and use of U , there will always be a wide range of choice in formulating hypotheses of a general character.⁶

In order to adapt semantical concepts of extension and intension to pragmatics (in the sense of Carnap and others), detailed analysis of concrete empirical procedures is highly desirable. In terms of operations, concepts of

intension are not necessarily vaguer or more speculative than those of extension. The objection raised against intensional concepts may indeed be effectively met as suggested by Carnap (1956: 60): "If for a given semantical concept there is already a familiar, though somewhat vague, corresponding pragmatical concept and if we are able to clarify the latter by describing an operational procedure for its application, then this may indeed be a simpler way for refuting the objections and furnish a practical justification at once for both concepts."

“You Assert This?” An Empirical Study of Weight Expressions

Introduction

“Man is descended from some lowly organised form.” This is one of Charles Darwin’s conclusions in his *Descent of Man* (1882: 788). The sentence is interesting from many points of view. He uses the vague term *lowly organised form*. For his moderate defenders it was possible to use broad interpretations; antagonists tended to narrow it down, and won over the media: Darwin was understood simply to say that we descended from apes. From the point of view of this article, the terms *show*, *attempt to show*, and *certainly* are interesting. “Show” may be plausibly interpreted as implying verification (of a hypothesis). Darwin uses a large diversity of weight expressions, some of them complex: “the fashions of savages are far more permanent than ours; and whenever their bodies are artificially modified, this is *necessarily the case*” (ibid., p. 583).

It is plausible that the term *necessarily* here is used in a wider sense than in contemporary philosophy of science, but exactly what did Darwin here *claim*?

His complex (“higher order”) weight expressions pose questions that need painstaking research. A second example: “[i]t is . . . *impossible*, as we have *seen*, to *maintain* that this *belief* [in God] is innate or instinctive in man” (ibid., p. 612; my italics for weight expressions). “Impossible to maintain” is clearly not meant or entirely meant to be a sociological or psychological hypothesis, nor one of formal logic presumably, but a kind of hypothesis of composite character—like so many other weight expressions.

This article was reprinted with permission from *Empirical Logic and Public Debate: Essays in Honour of Else M. Barth*, edited by Erik C. W. Krabbe, René José Dalitz, and Pier A. Smit (Amsterdam and New York: Rodopi, 1933), 121–32, 35.

Against research projects with the aim of investigating complex weight expressions in Darwin’s writings, one may object that he never had reason to mean anything very definite when he used such expressions, and that whatever he may have meant, it was nothing original: he just followed the customs of his research community. Even if his *definiteness of intention* was rather limited, there are sets of transintentional interpretations of contemporary interest, and even those within his reach are of interest when studying how assertions function in research. Just one more example from Darwin: “[i]t *cannot be supposed*, for instance, that male birds of paradise or peacocks should take such pains in erecting, spreading, and vibrating their beautiful plumes before the females for no purpose” (ibid., p. 616). Implied are, I think, some strong assumptions of purposefulness that, if accepted, make it more or less logically inconsistent with those assumptions to suppose the birds in question do not have a purpose for behaving as they do.

The pragmatic aspect is often clear, for example in Frederic B. Loomis’s classical *Evolution of the Horse* (1926: 105): “between any two variants [of *Mesobippus bairdi*] there are so many transitional forms that it has *proved most convenient to regard* them all as one species.” Feelings, but not mere feelings, are highly relevant: “[a]s none of the known species of *Parahippus* *can be considered* the immediate progenitor of . . . , we *feel* that the change took place on the plains in northern America” (ibid., pp. 124–25).

High-level textbooks of theoretical mechanics and similar fields contain a smaller diversity of weight expressions, but some are complex and important. “Dabei ist allerdings *die idealisierende Annahme* eingeführt, dass . . .” (Müller and Prange 1923: 62). The “idealizing” assumption introduced is the fundamental one of solids being adequately dealt with as mere material points, “points of mass.” How does this assumption affect the weight of other assertions in the book?

If hard-pressed, scientists tend to introduce successively more complicated weight expressions.

Do We Know Much About the Use of Weight Expressions in Science?

Consider the following start of a communication between *A* and *B*:

A: The nucleus is the controlling center of cellular activity.

B: You *assert* this?

A: Yes.

B: So, you could also formulate it this way: "it is true that the nucleus is. . . ."

A: I could not for at least three reasons: First, I would not start with "it is true that" without something being contested or for other special reasons. Second, the assertion is in principle only a scientific hypothesis. To say it is true is to use too strong a word. Third, the formulation admits many different interpretations, a family of closely related assertions. Some members of the family I would class as fairly uncertain or even slightly erroneous. Other members I would say are beyond doubt correct. I would, if pressed, even say they are true. The situation is, in short, rather complicated.

The trend of *A*'s answers is toward greater complexity of assertions. His second answer consists of eight sentences, if we interpret "sentences" not in a grammatical sense, but as strings of words limited by full stops. Suppose the communication continued. *A*'s fifth answer might well consist of 100 sentences, all part of an adequate answer to *B*'s question "You *assert* this?"

The above communication shows that *B* is interested in what weight, in at least one sense of "weight," *A* attaches to his utterance about the nucleus. It turns out that *A* is clearly conscious of his own usage of certain terms, what I shall call his "weight expressions."

Using an old epistemological distinction, "knowledge by acquaintance" versus "knowledge by description," we may admit that *A* manifests more than usual knowledge by, or *as*, description, not just knowledge by, or *as*, acquaintance. *A* is able to articulate insights about his own use of expressions.

The investigation of weight expressions has the aim to increase our knowledge by description. We are well acquainted with the vocabulary of our mother tongue, but our knowledge on the level of science may be next to nil.

The short interaction between *A* and *B* exemplifies a variety of weight expressions. "It is true that . . ." is not a very common expression. In the context of the first four steps of the above communication, the expression "I *assert* so and so" may or even must be interpreted as a weight expression, depending on our definition. The same holds for ". . . only a scientific hypothesis." Without the "only" we get a somewhat heavier or stronger weight expression: "scientific hypothesis." Furthermore, the communication exemplifies instances of "fairly uncertain," "slightly erroneous," "beyond doubt correct," and the less strong "I would say are beyond doubt correct." The last expression, "I would, if pressed, *say* they are true," like the foregoing, belongs to the many complicated utterances expressing complex attitudes toward the status of assertions.

Comparing the use of "It is probable (that such and such)" with "I found (that such and such)," people are more sure that they know what they themselves mean when they use the latter expression, or at least they are more willing to enter into detailed explanation. In every case, however, there is a limitation of definiteness of intention in certain senses of that term. It is natural to admit that we do not mean anything very definite when we talk in a relaxed way in everyday life.

This brings up questions of interpretation, especially expressions like "I interpreted T_0 to mean T_i ," where T_0 is a sentence heard and T_i is a sentence within a group of sentences $T_1, T_2, \dots, T_i, \dots, T_n$ acknowledged to express interpretations of T_0 . Among the answers to questions like "When you heard T_0 did you interpret T_0 in the sense of T_i , or differently?" there is one kind of special interest, namely, answers like "I don't know." They indicate that these people simply do not find any basis for answering. They acknowledge T_i as a possible, even plausible, way of understanding T_0 but feel they don't know whether they actually understood T_0 that way. The "*nescio*-answers" ("I don't know" answers) remind us that when people listen and understand, for example, a part of a speech, there are no or very few "conscious" acts of interpretation. Avoiding the term *conscious* we may say there are few instances of the listener saying to himself " T_i is meant" or occurrences of rudimentary articulations of something to that effect.

Outside small expert groups, the kind of weight expression "(such and such) has been *refuted* (by so-and-so)" is used with a low definiteness of intention. Two groups of students get in touch with requirements of greater

definiteness: law students and students in (some) philosophy of science courses. In the latter, a theory is sometimes said to have been refuted if at least one observation is clearly inconsistent with what the theory predicts. That is, a sufficient condition of correct use of an expression of the kind "theory such and such is refuted" is either stipulated or formulated as a description of what is the common view within a scientific community. In other courses it is said that, strictly speaking, no theory is refuted, because the relevance of the observation depends on the correctness of an indefinite number of assertions expressing the observational conditions, for example, the purity of certain chemicals if the observation has to do with results of a chemical reaction.

The expression "strictly speaking" is of interest here because it is used by people who believe they *know* which usages (ways of speaking) are "strict" in some prescriptive sense. These people indicate different bases of their beliefs. Exactly which bases?

Whatever the case, an empirical investigation of the weight expression "(such and such) has been *refuted* (by so-and-so)" may take years of work by a collaborating group. It is likely that in the long run, the investigation would come to be regarded as less a study of a verbal expression than an investigation of the methodology of hard science or jurisprudence, or of substantial parts of sciences of every kind.

Knowledge as Calcified Research

This article is not meant to motivate colossal research projects but to stimulate awareness of unaddressed problems. Applied to education in colleges and in universities, and the process and dynamics of research, the aim of the article is to remind us that the distinctions true/false, known/unknown, probable/improbable, shown/not shown, refuted/not refuted are only a small fraction of expressions of significance found in attempts to apply the results of research in society. The term *result* is itself an important expression. It is often used almost synonymously with "what is *found* through research," a pervasive metaphor in the political discussions at Rio de Janeiro in June 1992. "What has science *found out* about the climate?" How is "finding" to be understood in research? We are back to the history, methodology, and philosophy of science, or rather, of scientific research. The search

itself is a restless, limitless endeavor with no fixed doctrines whatsoever, because doctrines imply texts, and texts imply interpretations. Scientific *knowledge* is perhaps a name for a calcified, maximum-entropy state of affairs. A section of a scientific encyclopedia without weight expressions is analogous to a clip of a movie.

The intricate *historical* development of a weight expression has been studied carefully in only one case: the expression “ . . . is proved.” The *quod erat demonstrandum* has, especially since the sixteenth century, been studied intensively. After Hilbert and Gödel, the development is beyond the scope of understanding of all except the specialists, but what we all can do is deepen our definiteness of intention when it is called for (and not bother others when it is not called for). The authoritative text of Euclid's *Elements* is extremely poor and uniform in its use of weight expression. Why?

How does the term *scientific knowledge* function relative to the hundreds of strong and weak, simple and very complex, weight expressions used by active researchers?

If it is known that gold is heavier than silver, then gold is heavier than silver. If it is known that p , then p . To say “It is known that p , but it may be false that p ” is felt to be awkward. Today, however, it is common to say that all scientific knowledge is hypothetical. “Any part of scientific knowledge may be wrong, mistaken.” If it is scientifically known that p , then p or not- p —a modest claim indeed! Of course, the claim is stronger, but just how strong? In fact, there is not one claim but hundreds: corresponding to the hundreds of weight expressions alive in active research along its long frontier. To say that all scientific knowledge is hypothetical has been adequate as an opening to a discussion in which neither the term *knowledge* nor the term *hypothetical* may have any important function. A manifold of expressions takes over.

Too many gifted young people are overwhelmed by the requirement of “knowing,” especially in hard sciences education. It is difficult to change this, but more courses in “physics appreciation” will certainly help to increase motivation, to mention only one factor. The ideal appreciation courses appeal to the imagination, the adventurous, the process of *search*, not knowledge. Another factor is a shift to scenarios and inventions rather than discovery of new facts: the theories in modern hard science are primarily inventions, creations of speculative fantasy, and only touching observa-

tion at infinitely few, but decisive, points. Therefore, the weight expressions are only rarely those of knowledge, fact, probability, verification, or even falsification. If students could be invited to read texts more suggestive of the dynamics of living research, they would feel the relevance of the life of hard science to their own way of life.

The *pedagogical* importance of the study of weight expressions owes, therefore, to several factors. One is the lamentable poverty of weight expressions in contemporary textbooks and popularizations. The intricate process of simplification, condensation, and standardization neglects what is actually *claimed* by researchers, sentence by sentence. When complex and weak weight expressions are left out, the scientific enterprise as a vast human cultural enterprise is largely forgotten.

An Inventory of Weight Expressions in Science

In what follows I shall use data gathered in the 1950s as part of an unpublished study of weight expressions.

To secure comparable units of text from different scientific works, we calculated the number of "letter places" per page and also the number of pages necessary to obtain a standard unit of investigation, 120,000 letter places. As a letter place we counted the place of a single letter or an open space between two words or between two sentences.¹ Textual pictures, tables, and footnotes were not subjected to calculation, nor were quotations from other authors. A unit of 120,000 letter places in a text we called a "population." The number of pages per population in our collection of data ranged from about 40 to 120.

In all, every weight expression in 70 populations from 62 works was underlined. In order to compare scientific texts on a technical level with other kinds of texts, we chose some works that were articles and books of a different character: textbooks of science and popularizations. The works were numbered 1 to 62. The number combination 31,2 stands for population number 2 in work number 31. The underlining of weight expressions requires a fairly definite delimitation of such expression as opposed to others. The wording of the instruction on what to underline must be (1) interpreted in a similar way, and (2) applied in a similar way by different underliners. Our goal was to obtain more than 90 percent agreement or identity of un-

derlinings. A test confirmed that the instruction worked satisfactorily. There were, of course, discrepancies. In the case of population 31,2 the first investigator underlined 72 expressions and the second underlined 79. Moreover, the first underliner classed an occurrence of "appear" as a weight expression whereas the second did not, and the second classed as a weight expression an occurrence of "appears" that the first did not. The discrepancies were attributable to different interpretations of the *context of the occurrences*.

Why not formulate a fairly precise definition of the term *weight expression*? That would solve many questions. Roughly, this is the reason: it would regulate the collection of data in agreement with a *special preconceived concept* within a large field not yet charted.

Four populations concerned mathematics, two statistics, two mechanics, one astronomy, nine chemistry, eight geology, four paleontology, two zoology, seven biology, three physiology, five psychology, two psychiatry, two sociology, two economics, two science of law, eleven history, and four philosophy.

Thirty-six of the populations were classified as "technical" in the sense of not "mere" textbooks and not popular; twenty-eight were classed as textbooks, and six as popular. Sixty-two texts were written in the twentieth century and eight in the seventeenth, eighteenth, or nineteenth century.²

Forty-three were written in English, nineteen in German, and eight in Norwegian. From the point of view of methodology it would have been preferable to have only one language represented. The translatability of nearly all expressions is remarkable, however. It is difficult to find any use difference among, for example, "it is the case that," "es ist der Fall dass," and "det er tilfelle at."

The Frequency of Weight Expressions

The average frequency, all seventy populations taken together, is 20.3 weight expressions per 10,000 letter places. These expressions consist on the average of 2 words each. The average number of words per 10,000 letter places is about 1,600. This means that about 2.5 percent of the total number of words are weight expressions. That is about 40 words per 10,000 letter places, 40 out of 1,600 words. Thus, the weight expressions form a significant part of scientific texts.

Table 2. Most Frequently Used Weight Expressions.

English Expressions	German Expressions
1. show (that such and such)	1. ergeben (es ergibt sich dass . . .)
2. see	2. gelten, gültig
3. find	3. annehmen, Annahme
4. prove, proof	4. zeigt
5. fact	5. scheint, erscheint
6. assume, assumption	6. wahrscheinlich, Wahrscheinlichkeit
7. seem	7. beweisen, Beweis
8. probable, probably, probability	8. offenbar
9. know, knowledge	9. sehen
10. evident, evidently	10. möglich, Möglichkeit

Popularizations showed an average of 13.6 weight expressions per 10,000 letter places, textbooks 15.6, and (scientific) technical writings 25.0. This confirms a tentative hypothesis that there is a general decline in the use of weight expressions with distance from the live process of scientific research. Therefore, students reading textbooks do not get an intimate contact with how it feels and what it takes to do research and to assess the weight of what is asserted or announced.

Comparing authors, we find clear differences. Some authors tend to repeat the use of certain weight expressions and to use only a few different ones. Others use weight expressions infrequently but employ a relatively high number of different ones. The relation between the total number of weight expressions used and the number of different ones is found to be 4.44. The relation varies from 2.16 in population 55, a popular English work on history, to 10.08 in population 29, a German textbook on mathematics.

The meagerness of data does not warrant close statistical analysis. The investigation was planned as a pilot study, opening up a promising field.

In order to obtain a rough idea of relative frequency, we shall refer to ten populations, five English (populations 2, 3, 4, 5, and 6) and five German (populations 7, 8, 10, 22, and 27). In table 2 we have listed in order of frequency the ten most frequent weight expressions in the two main languages. The classification of “assumption” as a weight expression depends heavily on the context. Sometimes it is a near-synonym for “working hy-

pothesis." Sometimes the researcher is only interested in what logically follows, if such and such is used as a premise.

The two lists shown in table 2 are fairly similar, 1 = 4, 2 = 9, 3 = 1 (?), 4 = 7, 5 = ?, 6 = 3, 7 = 5, 8 = 6, 9 = ?, 10 = 8. In the German list we have *gelten* (to hold good) and *möglich* (possible), which have no near-synonyms in the English list.

Many well-known expressions are absent from the list: true, false, mistaken, (not) the case, falsified, verified, confirmed, certain, likely, corresponding with reality, really so.

Strong Versus Weak Claims

In population 30,2 we find the sentence "It seems clear that the nucleus is the controlling center in cell activity." We interpreted this to express a weaker—more moderate, less weighty—claim than would be expressed by "The nucleus is clearly the controlling center in cell activity." As still weaker we would class "It seems that the nucleus. . . ." One might introduce a measure of strength, let us say from -10 to +10, but the arbitrariness would be too great. Instead, we class the expressions into four broad, significant classes—very strong, strong, weak, very weak—and attach a number to each: 2, 1, -1, -2. Expressions that we class as neither strong nor weak, but somewhere in between, or expressions that are very difficult to judge in terms of strength, we leave out of our statistics—a kind of 0-class. It is to be expected that different investigators show fairly big differences in how they class the expressions, perhaps more than 10 percent differences. Context plays a large role, and so do personal terminological idiosyncrasies. An expression like "it seems clear that" may for one author be a stronger claim than for another—"it seems *clear* that" versus "it *seems* clear that." The one may habitually use "seems"; the other, rarely and with emphasis.

Gottlob Frege was careful with his use of weight expressions, but in a famous letter to Bertrand Russell we may safely assume that a generally rather weak expression hides a stronger intended message: "Your discovery of the contradiction caused me the greatest surprise and, I *would almost say*, consternation (*Entsetzung*), since it has shaken the basis on which I intended to build arithmetic." Frege *was entsetzt!* The weight expressions have a negative function: to admit uncertainty, to express qualifications, to shy away from crude,

simple assertion. Using the above scale we can therefore expect that the sum for each population is a number less than zero. Actually, the general average for all seventy populations is found to be -14 . The range is from -212 in population 18, a series of English articles on psychology, to $+190$ in population 5, a technical English work on statistics. It is tempting to say that the difference reveals the modest epistemological status of psychological research and the established high status of theoretical statistics. (An investigation of opinions among scientists on statistics *in practice* showed a remarkable degree of scepticism; this holds, for example, for the master statistician Trygve Haavelmo.) The data do not admit anything but conjectures. As could be expected, there are more weak and very weak expressions used in technical works than in textbooks (averages -29 and $+2$). Does this mean that consumers of research are more uncritical than producers?

Expressions Referring to Human Activity or Experience

A distinction of considerable interest is that between weight expressions referring to human relations and those that either do not invoke any such relations or do so only in an indirect or implied way. Calling something a fact or a truth is an example of the latter; calling something an assumption is "strictly speaking" talking about a human act, usually in relation to an opinion or theoretical premise that is accepted as tenable. Saying that something is proved refers only to a human action, but it is *implied* that if a theorem is proved, it is true or valid. "Valid" in some contexts and some interpretations refers to human society; in other cases, it is as faintly suggestive of human relations or affairs as "true." It is notable, however, that most people strongly associate the term *true* with the very human activity of testing. "That it is shown" and closely similar homocentric expressions are the most frequent kind of answer to the question "What is the common characteristic of all that is true?" among people who are not professional philosophers (Naess 1938). Professionals may react with a depreciating remark that there are infinitely many truths that are not "shown" and never will be shown. But nonphilosophers seem to *presume* that "it" in "it is true" and similar expressions refers to something that has already been considered by human beings. The abstract use of the term is often not accepted. People find the thought queer that there is or even exists at any given moment an

infinity of unknown truths about unknown things. A book *could* be written about each individual drop of rain in the Amazon rain forests, thousands of potential truths and errors about each drop—but people are not impressed!

Sometimes, not often, nonprofessionals are able to *articulate* fairly pragmatic views about truth. In short, the expressions “it is true” and “it is shown” have many functions in common. Studied from one perspective, every function can be defined in terms of human relations. Each occurrence of each of the weight expressions may be said to have a function within a larger whole, a *Verhaltensweise*, only in part verbal.³ From a different perspective, we may, and should, define them as without explicit relation to human beings. I have called such weight expressions *homofugal*—escaping from the human. The others I call *homopetal*—human-seeking.

The attempt to classify expressions consistently as homopetal or homofugal leads to complex studies of context. The weight expressions “evident,” “evidently,” and “evidence” function in most contexts as homopetals. Human beings experience evidence when considering certain assertions. In a phenomenological context, however, we find descriptions of how human beings may be confronted with the evident as such much as they are confronted with a wall. Edmund Husserl in his monumental *Logische Untersuchungen*⁴ talks about a confrontation with the inescapable evidence of the law of contradiction, not as an experience of evidence but as something inherent in the law. The evidence is not on the side of a subject experiencing evidence. Nothing human is implied when the subject is confronted with the simple *that it is so*, the *Sachverhalt* itself. When confronted with a tiger we should be aware that we are not confronted with an experience (*Erlebnis*) of a tiger. The evidence of the principle of contradiction (properly understood) is a kind of real tiger in this respect. In short, practical application of the proposed classification of homopetals is “relational” in the sense of being dependent on philosophical premises being accepted. In certain early Husserlian contexts, *evident* and *Evidenz* are homofugal weight expressions, and perhaps also in many other contexts.

Among the introductory textbooks investigated, I wish to mention Ludwig Kiepert's *Grundriss der Integral-Rechnung* (1920). It belongs to a different mathematical-pedagogical culture than that of today. There is no sense of cleverness and hurry in its pages, no impression of life in the fast lane. The “progress,” step-by-step, is so slow, the elementary examples so

many and so *ausführlich* (exhaustive), that it can be read in the same way we read an entertaining book on history or gastronomy. Space is ample—why not use 932 pages? The paper is rough and ecologically defensible; Germany in 1920 could not afford luxurious, chemically complicated paper.

The weight expressions in this text are few and simple: something is *found* or *proved*, something is *valid*. There are weight expressions, but the atmosphere is one of confidence and equanimity. The context makes it clear that the seemingly bold expression “for the sake of simplicity the assumption is made that . . .” (Kiepert 1920: 620) is not a weight expression.

The texts written in past centuries were few: Robert Boyle’s *The Sceptical Chymist* (1661); Malthus, *On the Principles of Population* (1798); Thomas Henry Huxley, *Man’s Place in Nature* (1863); selections from Spinoza; Adam Smith, *The Wealth of Nations* (1776); Charles Darwin, *Origin of Species* (1859) and *The Descent of Man* (1871). There is no marked difference in the use of weight expressions correlating with time in our data, but I suspect that with more data, significant differences would be found in the literature of physics (more reference to human activity—for example, assumptions).

An Ontological Reflection

A short conversation:

A: Your theory developed in your recent book is admirable. All through the book you make an assumption, let us call it *P*, for short. Don’t you assume *P*?

B: Yes, I do.

A: In the book you use the weight expressions “probably,” “evidently,” “scarcely correct,” and others. If the assumption is false, would you have to change those expressions all through your text?

B: Of course, practically all of them. My weight expressions would, on the whole, be drastically changed, but certainly they would not be more complex. The text would have been far more complicated.

In natural science, untestable or untested assumptions play an increasing role. This makes it less adequate, sometimes even squarely misleading,

to use the simple, familiar homopetal expressions accepted at the level of activity in the laboratories. At the observational level, the enormity of technical equipment overshadows the old dominion of just seeing that such and such is the case.

When a set of assertions A is used as a set of premises for B , B for C , C for D , and only D is on the observational level, the homofugal weight expressions are misleading, except to characterize derivations within formalisms. There are infinitely many sets of premises from which B follows, and infinitely many from which C follows. Because of the theoretical levels of A , B , C , the case is different from the derivation in "All fish are warm-blooded, all whales are fish, therefore all whales are warm-blooded." The set of premises here is close to the observational level. In the hard sciences, there are long chains of derivation within the nonobservational sphere.

The long derivation chains lead away from the Einsteinian ontological view of physical reality toward the conventionalism of Henri Poincaré and the "conventionalist" school. A more appropriate name would be "assumptionism." Niels Bohr, in his famous Moscow discussions, showed the way: quantum physics may be regarded as a set of abstract structural assumptions, freely chosen, from which we can derive conclusions tested on the everyday level of setting up experiments and observing light signals.

There are heuristical limits to the choice of possible physical worlds, but no theory is more "probable" than any other. "From probabilism to possibilism?"⁵

Back to the short conversation at the head of this section. When ten more or less observationally untestable assumptions are made along a chain of derivations, negating one or more of them results in 1,023 alternatives, none of them contrary to observation. Research does not consist in trying to find out which theory is true, most probable, nearest to what is the case. Weight expressions still have a crucial role, but it tends to be a complex one in terms of human activity and experience. Ontology need not turn toward subjectivism, but toward appreciating the world as experienced in everyday life, listening to the physicists who are engaged in work with models of the (very) abstract *structure* of reality.

Can Knowledge Be Reached?

My thesis in this paper is that there is no amount or quality of evidence such that if that amount or quality is reached, then truth is reached. If, therefore, a proposition must be true in order to constitute knowledge, knowledge is never reached. If certain standards of evidence are satisfied I have the right to *say* “I know,” and the right does not depend on how one answers the question whether it is right *what* I say.

The conclusion of this paper will be that knowledge cannot be reached. Or rather, that in an important sense of ‘knowledge’ and of ‘reaching’, knowledge is not something that we can reach. We may already possess it—and I do consider both myself and others to know quite a lot—but I cannot see that I am able to offer a philosophically satisfactory account of how we could possibly have come nearer to it until a definite event happened: we reached it.

Formulated and interpreted with care, this conclusion is, I think, both nontrivial and true. It is restricted, though, to those concepts of knowledge that require that in order to reach knowledge, we must reach truth, and restricted also to those concepts of truth that require that in order to be true, what we say must be so.¹

There is an old and distinguished family of definitions or criteria of knowledge with a requirement that for something to be known, it must be true, and for something to be true, it must be the case. The truth requirement may be thus formulated: something cannot both be known to be so and yet not be so.

This article is taken from a lecture delivered at Oxford University in October 1969 and was reprinted with permission from *Inquiry: An Interdisciplinary Journal of Philosophy* (New York and London: Routledge, Taylor & Francis Group) 4 (1961): 219–27.

The expressions “to be so,” “to be the case,” and “to be true” are very near in meaning and function in the context relevant to our problem. If we substitute “to be true” for “to be so” in our formulation of the truth requirement, we arrive at a rather modest claim, closely related to the truth requirement: something cannot both be known to be true and yet not be true. I mention this in order to stress that giving up the truth requirement of knowledge would lead to paradoxical, or at least very queer, results.

Within this family of definitions, or criteria, or sets of necessary and sufficient conditions of knowledge, there is a subfamily with three requirements: one can only be said to *know* that *p* if (1) one is sure that *p*; (2) one has adequate grounds for being sure that *p*; and (3) *p* is true.

The requirements may be transformed into a questionnaire of three questions. Some such questionnaire cannot easily be avoided if the definitions or criteria are to be used in concrete cases by people who want to make sure that they themselves or others *know* that such and such is the case, and not just believe it, assume it, and so on.

Suppose I take it for a fact that Mr. Nixon’s opinions concerning the Chinese offshore islands are about the same as President Kennedy’s. Suppose also that in Mr. Nixon’s behavior I find indications that he himself either *knows* this to be the case, or has *made a guess* to that effect, or for some reason or other has chosen to perform some of his actions on *the assumption* that this is the case, and so on. If, then, I want to answer the question of whether Mr. Nixon knows, or makes a guess, or assumes that such and such is the case, I may decide to make use of the following kind of questionnaire:

1. Is he sure that *p*?
2. Does he have adequate grounds for being sure that *p*?
3. Is *p* true?

In this questionnaire the third question is different from the conjunction of (1) and (2).

Now, however, we come to the problem children of our distinguished family, the criteria that *I* know that *p*:

2. “I know that *p*” — “I am sure that *p*; I have adequate grounds for being sure that *p*; *p* is true.”

In asking myself, or being asked by others, whether I know p to be the case, what am I to do when confronted with the third requirement, that p be true? If I am trying to decide whether *I* know or don't know p to be the case, what, then, is the relation between the first two requirements and the third one? Is it really a new question?

For the sake of an easy survey I write out both the third-person questionnaire, where I answer questions about a third person, and the first-person questionnaire, where I answer questions about myself:

Question 1: Is he sure that p ?

Question 2: Does he have adequate grounds for being sure that p ?

Question 3: Is p true?

Question 1: Am I sure that p ?

Question 2: Do I have adequate grounds for being sure that p ?

Question 3: Is p true?

There is some sort of incongruency between the two questionnaires. In deciding whether *he* knows, it is *I* who answer the question whether p is true, and, of course, I do it on the basis of my own beliefs and grounds—to which there is no reference in the questionnaire. The third-person questionnaire is that of a bystander or observer, or it is that of an editor of an encyclopedia of knowledge, such as, for example, Otto Neurath, whose views about knowledge, according to Bertrand Russell, were characteristic of an editor who is not also a contributor.

Faced with question 3 of the first-person questionnaire ("Is p true?"), I shall once more ask myself, Do I have adequate grounds for being sure that p ?—or I shall frantically search for something more than evidence, say a guarantee of truth. (Sometimes I firmly believe that I have a guarantee, but, speaking generally, I adhere to the view that there can be no guarantee for the truth of a statement whose negation is not some sort of contradiction.)

If I have already answered yes to the question about adequate grounds, the question "Is p true?" will either be interpreted as a repetition of the question about adequate grounds, or it will be interpreted as unanswerable

or awkward, like the question “Irrespective of adequate grounds and my own conviction—*is p* true?”

Nonphilosophers, and perhaps philosophers too, employ concepts of truth in their everyday life that are completely independent of requirements about being sure, and completely independent of requirements about adequate grounds or the right to be sure. I have called such concepts, or conceptions, of truth homofugal and contrasted them with what I have called homopetal conceptions. In the homofugal conceptions there is no reference to human conditions or human activities.

Not without a struggle with my own inclinations, I have long accepted a homofugal conception of truth as inevitable. Given a homofugal interpretation, however, the first-person questionnaire is a bad questionnaire, since the third question cannot then be answered. That is, it cannot be answered on the basis of rational considerations.

If, on the other hand, we accept a homopetal conception of truth, and interpret the third question accordingly, the question will be redundant, since the answer to it will follow from the answer to question 1 or 2.

Thus it seems that for both conceptions of truth, the questionnaire is ill conceived.

Before I continue, I ought perhaps to mention how I interpret “adequate grounds” and “the right to be sure.” According to one interpretation, grounds are adequate only if they guarantee truth, and nothing less than such a guarantee gives one the right to be sure. This is not how I use these expressions in this paper. According to another interpretation, which *is* how I use these expressions, grounds are adequate if definite, but variable, standards of evidence are satisfied, and when they are satisfied, one has also the right to be sure.

I shall now put forth a theory or an explanation, or at least a few comments, as to *why* the first-person questionnaire is felt to be so awkward. Some people have found my explanation highly speculative and metaphysical, whereas others have found it simple and commonsensical.

In saying “*p* is true” I do not intend, or very often do not intend, to express anything that has to do with *my* relation to *p*. I just tell that *it is so*, that what *p* says *is the case*. I enjoy a homofugal attitude or bent of mind. Or, if I am a staunch ontologist, I shall say that I am absorbed in the world of objects. At least, these are the words that seem to fit in retrospection.

I am, however, never safe in my enjoyment of truth. A shift may occur at any moment that makes me see, or search for, *my* relation to truth, or *my* relation to *p*. Of what kind is my access to truth, that I can utter, as a rational being and with a sober voice, "*p* is true"? I want to get a picture of myself grasping truth and holding it in my hands.

Whether or not such reflection results in reassuring myself that *p* is true, the natural, and adequate, expressions of my reflection are homopetal, not homofugal. I may feel surer than ever that Francis Bacon did not write *Hamlet*; that is, I am more positive than ever in my answer to question 1; or more than ever do I consider my grounds as adequate and my methodology unassailable—and in saying so, I repeat my answer to question 2. I shall not make use of the expression "*p* is true" or any other homofugal expression, however, because my attention is egocentric. Perhaps, instead of answering question 3, I shall say, "I am more convinced than ever that *p* is true," but from that it does not follow that I am willing to say simply "*p* is true."

There is, in some sense, no way back from the evidence attitude to the attitude of simply saying what is. On the other hand, the simple attitude of asserting truth does not have to lead to questions of evidence.

So far, I have discussed the awkwardness of first asking for evidence and then—immediately afterward—for truth. Maybe a simple change, asking for truth first and then for evidence, will save us from trouble. Professor Chisholm, in his book on perception, places the truth requirement as the third one, but Professor Ayer, in *The Problem of Knowledge*, places the truth requirement as the first one:

I conclude then that the necessary and sufficient conditions for knowing that something is the case are first that what one is said to know be true, secondly that one be sure of it, and thirdly that one should have the right to be sure.

(Ayer 1962: 35)

Reformulated, this piece of text may well be taken as a member of the family of definitions under consideration. A corresponding questionnaire in the first person would run as follows:

Question 1: Is what I say I know true?

Question 2: Am I sure of what I say I know?

Question 3: Do I have the right to be sure of what I say I know?

For the present purpose, these questions may be reformulated as follows:

Question 1: Is p true?

Question 2: Am I sure that p ?

Question 3: Do I have the right to be sure that p ?

As an oral questionnaire this one is likely to be more successful than the previous first-person questionnaires, because here the subject is asked about p before he is asked about his relation to p .

Suppose I answer yes to all three questions but then get worried about the first question and change my answer from a simple "Yes, it is" to "I am sure, and I have the right to be sure that p is true." Such a change would seem to me irrational; that is, I cannot see that I could give it a rational justification. Any such justification would amount to a rational reconstruction of the transition from truth attitude to evidence attitude.

It seems that saying, of a given p , "It is so," "It is the case," "It is true," or simply asserting p , is an act for which there can be no adequate rational reconstruction. Saying "It is so," etc., does not entail, and is not entailed by, any statement about adequacy of grounds or firmness of conviction. Therefore, accumulation of evidence makes me say "There are now more grounds than ever for taking p to be true" or "I am now more justified than ever in my conviction that p is true," rather than repeat "It is so." As long as my attention is focused on the increasing evidence, or as long as I am not absorbed in immediate perception or intuition, my verdict is adequately expressed in homopetal terms only.

The transition from truth to evidence, or vice versa, might perhaps be understood in terms of levels. If I enjoy truth while absorbed in the amassing of evidence, my use of the expression "It is true" refers to second-order statements: "That the weight of my evidence is crushing, is as simple a truth as can be." "My conviction is total. That is the simple truth." "You earned your right to be sure that the gun was unloaded, that is true; but, God bless your soul, you were mistaken in saying you knew."

If reflections enter the scene while I am enjoying truths of the second

level, the homofugal terms will disappear from that level, and if they reappear, it will be at the third level; and so on.

At any level, a philosopher may point to something I assert, enjoying truth, and correctly comment that I believe I have knowledge. If, however, the philosopher is inclined to argue in favor of scepticism, he may point instead to the transition from enjoying truth to collecting evidence and correctly comment that no volume of evidence will regain for me my first enjoyment of truth.

One position that might be called sceptical—although I do not think it ought to be called that without qualifications—can be thus formulated: no evidence of a proposition is such that if it is available then the proposition is true.

If to reach truth, or to grasp truth, is to reach or grasp a guarantee that it is not falsity, we can say: truth or falsity cannot be reached by increasing evidence.

And if “knowledge” is defined in such a way that “to know that p ” implies “ p is true,” then we get another set of formulations characterizing the position: no evidence that p is so strong that if a person has that evidence, he knows that p . In other words: knowledge cannot be reached by increasing evidence.²

We might continue: if to understand or to see or remember that p is the case implies that p is true, then understanding or seeing or remembering that p cannot be brought about by increasing the evidence.

After all the talk about our not being able to reach such and such, we may feel better if we contemplate for a moment a case of our actually being able to reach something. I choose the case of reaching for an apple. In reaching out for it, my hand is brought continuously nearer to the apple. The act is brought to its happy end as I grasp it, and my grasping the apple is an event that stands out as something very different from my hand coming close to it. This difference is clear even if the “apple” reached subsequently is found to be of wood and therefore not an apple at all.

If I am too eager, or too drunk, I may overreach myself and grasp somewhere beyond the apple. There is nothing of all this in our groping for knowledge. We can perhaps estimate, or even measure, an increase in evidence, but not an approximation to knowledge. The event of grasping is not forthcoming, and nothing corresponds to reaching beyond. One can

even measure the distance of the hand from the apple. At a certain point, point zero, the hand reaches the apple. One can also specify an increase in evidence and perhaps find a scale for measuring this, but one cannot specify the distance from truth and the reaching of truth. One cannot fix a point zero in terms of evidence.

I have used the expression "truth attitude" a couple of times, meaning the attitude, or state of mind, of simply enjoying truths and asserting them once in a while, in contrast to the attitude, or state of mind, of collecting evidence. Now, it seems that I can *say* "A is now enjoying truth" only about others. There is something queer about the statement "I am now enjoying truth," since it seems to presuppose reflection inconsistent with the very attitude it expresses. I say that I am at a level I cannot possibly be at the moment I say it, or think it. My friend may say to me, "You are now enjoying truth at level zero." If I answer, "Yes, I am," he can say, "No, you are not; you are enjoying it at level one." Meekly I admit it is as he says, only to be told that I am now at level two; and so forth.

This conversation need not worry us, however. It only reflects the fact that the truth attitude is linked to the act of asserting and does not disappear when reflection begins. It continues, but at level $n + 1$.

That knowledge cannot be reached is of little importance if it owes to the circumstance that we already have it. If we already have it, however, how are we to account for our strivings to increase evidence? Our situation seems to resemble the lot of the human race according to a certain doctrine of grace: good actions do not qualify for salvation, but they should be undertaken, and with salvation in view.

After all, our epistemological situation is not so strange. We strive to increase evidence because we think that we have often been mistaken, and most often when the evidence has been meager.

The successive editions of an encyclopedia of statements satisfying certain standards of evidence may rationally be expected to show fewer corrections the higher the standards. What would be the difference between an encyclopedia claiming knowledge and an encyclopedia claiming evidence only? It seems to me that there would be none, except in the subtitle and in the accounts of how the present edition differs from the foregoing. In the encyclopedia of knowledge there will be more acknowledgments of mistakes.

It is sometimes said that the sceptic insists on standards of evidence

that are impossible to reach. If this is characteristic of all forms of scepticism, then the view I advocate is not a form of scepticism. The requirement of truth is independent of the requirement of evidence. I do not quarrel with the standards of evidence; they have, perhaps, as a result of the prestige of the natural sciences, been placed too high in many fields of inquiry.

If, however, we do not make impossible standards of evidence part of our definition of scepticism—which, of course, we ought not to do—then the view I advocate is, I think, a form of scepticism, since it asserts the unattainability of knowledge. Whether it is a trivial form is a question we might cleave in two: one psychological and one logical. To the psychological question I can only answer that, to me, it is not a trivial form: I cannot but feel sorry and deceived, having imagined that in our search, and in particular in our research, there is a guarantee that we shall reach truth, and therefore knowledge. I can still *imagine* that the conditions of human existence were such that in our strivings we would sometimes reach knowledge and, of course, know that we had reached it, but I cannot imagine the conditions themselves.

Perhaps the *meaningfulness* I attach to my form of scepticism cannot be given a rational expression, with propositional content and logical consequences. If it cannot, then the answer to the logical question is not only that my form of scepticism is trivial, but that it is logically nonexistent. I think, however, that it can be given a rational expression. Even if I find it impossible to describe the conditions I imagine possible, and so must be content with a set of negations, like “Knowledge cannot be reached by increasing evidence,” and a set of rules limiting the applicability of such a maxim (that it must not include itself, etc.), such maxims are themselves meaningful propositions with consequences that can be derived by the usual rules of inference.

Husserl on the Apodictic Evidence of Ideal Laws

It is now more than fifty years since the publication of Husserl's *Logische Untersuchungen*. His argumentations are formulated with such care, thoroughness, and vigor, and many of his conclusions are so well substantiated by later research, that the book is justly regarded as one of the philosophy classics of the twentieth century.

There is a quality in the *Logische Untersuchungen* that is not often commented on, but that deserves unreserved praise: the fairness and unbiasedness, the *Sachlichkeit* of his exposition of the doctrines criticized, especially those of psychologism. No charge is directed against imaginary adversaries, but against amply quoted assertions in definite texts. Considering the passion and consequence with which Husserl hammers out his views, this fairness is most admirable and makes his contribution singularly adapted to philosophical analysis.

In this article, some reflections are made about the character of the phenomenological approach. They do not conclude in any criticism of the main theses of *Logische Untersuchungen*, but interpret them in the light of a philosophy of philosophy that is diametrically opposite to that of Husserl.

Husserl continues the tradition of those philosophers who try to bring certain fundamental disciplines *in den sicheren Gang einer Wissenschaft* by starting from apodictically certain, definitely established, intuitively grasped truths. The present article represents the tradition of those who believe that the status of science will, if at all, be reached by continuation and expansion of that kind of research that has provided us with matter-of-fact knowledge, tentative hypotheses, and laws with different degrees of high probability.

This article was reprinted with permission from *Theoria: A Swedish Journal of Philosophy* 20 (1954): 53–63.

Husserl attacks “psychologism” and “extreme empiricism.” The first term is defined in section 17 of the first volume of *Logische Untersuchungen* as a kind of theory about the relation of psychology to formal logic: “Die wesentlichen theoretischen Fundamente (der Logik) liegen in der Psychologie,—Die Logik verhält sich zur Psychologie wie irgendein Zweig der chemischen Technologie zur Chemie, wie die Feldmesskunst zur Geometrie u. dgl.”¹ “In theoretischer Beziehung verhält sich also die Logik zur Psychologie wie der Teil zum Ganzen. Ihr Hauptziel ist es zumal, Sätze der Form herzustellen: Gerade so und nicht anders müssen sich—allgemein oder unter bestimmt charakterisierten Umständen—die intellektuellen Betätigungen formen, anordnen und zusammenschliessen, damit die resultierenden Urteile den Character der Evidenz, der Erkenntnis im prägnanten Sinne des Wortes erlangen.”² [*Editor’s Note:* See notes, pages 351–52, for English translations.]

The imposing development of symbolic logic as an independent science in recent decades and also its close connection with mathematics makes it difficult for us to understand how eminent thinkers such as St. Mill, Sigwart, and Erdmann could embrace the plainly untenable doctrines of psychologism. The development has no striking parallel in causal sciences having human reasoning in logic and mathematics as their subject matter. The belief of St. Mill, Sigwart, Erdmann, Lipps, and Cornelius that such sciences under the leadership of the new psychology should be able to explain genetically and causally the development of the formal sciences was unwarranted or at least premature. The traditions of empiricism suffered from the defeat, and it is characteristic that many philosophers of our day who strongly emphasize their empirical and “antimetaphysical” leanings (Russell, Carnap, and others) are severe in their criticism of the dominant trends in empirical theory of knowledge of the nineteenth century.

The mistake of psychologism is only a consequence of a much deeper and more common mistake, according to Husserl. “Die psychologistischen Logiker verkennen die grundwesentlichen und ewig unüberbrückbaren Unterschiede zwischen Idealgesetz und Realgesetz, zwischen normierender Regelung und kausaler Regelung, zwischen logischer und realer Notwendigkeit, zwischen logischem Grund und Realgrund.”³

The psychologists seemed to believe that the *principium contradictionis* could be validated by an inference with psychological or, more generally,

factual premises. Many premises were offered. We cannot at the same time both believe and not believe in the same proposition. If we deny the laws of thought, we reaffirm them in our very denial. The principle of contradiction evokes in us complete evidence.

Because of and on the basis of these or other *Tatsachen* concerning human beings and their thinking, the *principium contradictionis* is valid—according to psychologism. It would be possible to reformulate pure logic as a factual science, a kind of anthropological discipline.

Husserl maintains that a “reformulation” along these lines annihilates formal logic, and there is scarcely anybody who would disagree with him today on that point. From the invalidity of $p \ \& \ q$ and $\sim (p \ \& \ q)$ in the propositional calculus, one could not after the “reformulation” rigorously infer any other proposition, let us say $p \ \& \ q$ and $p \vee q$. From the inability to think the former does not “follow” the inability to think the latter. There may be constant confirmation of both instances of inability, and this justifies an inductive inference, but no proof of the propositional calculus could be formulated on that basis.

On the other hand—and this is often forgotten in the laudable effort to stamp out every trace of psychologism—the program of a science of science remains. A science of science must include research dealing with human scientific activity and its products—including pure logic, pure mathematics, and pure theory of knowledge in the sense of Husserl. Among the objects studied we find the calculus of propositions in various modifications and all the proofs, axioms, rules, and metamathematical devices developed in recent times. It is part of the task of empirical philosophy to explore the possibilities of a *kausale Tatsachemwissenschaft*, of establishing *reale Notwendigkeiten* and *Realgründe*. On the basis of such research it is in principle legitimate to expect *predictions* of experiences of apodictic evidence and the establishment of *die Logik als normative und praktische Disziplin* (Husserl 1913: 1: 1). Moreover, all of this must be done without committing empirical philosophy to any form of psychologism.

Husserl does not reject the possibility of such sciences of the real—he only emphasizes that their laws can neither prove nor disprove any strict law, for example, of the kind we require in order to develop formal sciences.

In the realm of the ideal laws in the sense of Husserl, there is necessity and complete exactness of content. Insofar as sentences are intended to ex-

press ideal laws and their interconnections, their *claims* must be to express necessary connections and complete exactness of content.

A researcher in pure mathematics may feel uncertain whether the proofs in his latest publication are all valid; he may even sincerely believe that the probability is less than 0.99 that all conclusions follow in complete strictness from the premises. This, however, will not induce him to change the claims from that of a strict proof to that of a reasonable argumentation. He stand or falls with his *proofs*.

We do not know which claims of living mathematicians and logicians are warranted and which are not. The only way of substantiating any claim is to go through the proofs repeatedly and increase their completeness and explicitness. If we, as part of this activity, make assumptions such as that oneself or the author of a text (actually) follows his definitions, or that he (actually) has certain intentions, these assumptions do not belong to the proofs. They cannot add to or diminish the validity of conclusions. According to Husserl, the validity is either apodictic or not of the kind required in an exact science. Any matter-of-fact assumption about definitions being followed introduces, it seems to me, something foreign to apodictic reasoning.

So much for pure and factual sciences in general. Let us then ask for instances satisfying the requirements of being parts of sciences. It is comparatively easy to give instances satisfying the modest requirement of factual sciences, but, if we are right in our interpretation of Husserl, formidable difficulties confront those who would establish parts of a pure science beyond doubt.

Husserl argues that we have apodictical evidence of pure or ideal laws, such as *modus barbara*, but the assertion that he or any other has this evidence does not belong to pure logic or any other pure or formal science. It belongs to a factual science concerning the relation of logicians (and others) to pure sciences. It is not necessary to conceive this to be psychology. It is enough for our argumentation that it is a science of facts or, more generally, a science about the real rather than the ideal.

Any assertion that a sentence interpreted as intended by a logician (or by myself, or by any other person) expresses an ideal law (and therefore something completely exact and of apodictic validity) is a sentence in principle belonging to the *Tatsachewissenschaften*. It does not belong to pure

science (*reine Wissenschaftslehre, reine Erkenntnistheorie*) but to a part of science concerned with certain kinds of objects and asserting things about those objects that may be true or false, depending on our shifting abilities of thinking and observing.

Factually existing sentences in treatises of pure logic may—as Husserl says—have the claim to express ideal laws, but from a claim does not follow its own satisfaction. Which sentences actually express ideal laws is a question admitting different answers, contradicting each other. The products of logicians are human products, and whatever their aspirations, the adequateness of their relations to the entities of the realm of the ideal is not apodictically evident. Those relations must be established inductively.

If it is objected that certain strict laws such as the *principium contradictionis* cannot be doubted because their very denial reaffirms the principle, the argumentation is already within the realm of *Tatsachengewissenschaften*: something is asserted about the possibility or impossibility of certain acts of thinking, doubting, and so on. The arguments against psychologism are applicable to such an attempt to validate that ideal law to which Husserl gives the name *principium contradictionis*.

The objection is also ill-conceived, because no argument in the foregoing paragraphs has been directed against the apodictic validity of the ideal laws. The subject matters under consideration are the products of existing mathematicians and logicians in their relation to ideal laws. Does any such product express an ideal law?

In the foregoing we have mentioned how Husserl conceives the difference between the real and the ideal sciences. We shall now consider what he offers as a criterion by which we can know beyond doubt that we have reached knowledge in the strict sense of the word, *Wissen im strengsten Sinne*. The criterion is *evidence*. Husserl elucidated what he means by *Evidenz* by calling it (defining it?) “unmittelbares Innewerden der Wahrheit selbst” and “die lichtvolle Gewissheit, dass ist, was wir anerkannt, oder nicht ist, was wir verworfen haben.”⁴ Evidence is, of course, to be distinguished from one’s merely being completely convinced about something. The difference is itself evident in certain special situations, namely, when we concentrate on ideal relations such as those expressed by the pure science.

Let us quote a passage in which Husserl describes how we as human beings can meet and grasp ideal existences and reach apodictic certainty:

Indem wir nun einen Erkenntnisakt vollziehen oder, wie ich es mit Vorliebe ausdrücke, in ihm leben, sind wir, “mit dem Gegenständlichen beschäftigt,” das er, eben in erkennender Weise, meint und setzt; und ist es Erkenntnis im strengsten Sinne, d.h. urteilen wir mit Evidenz, so ist das Gegenständliche originär *gegeben*. Der Sachverhalt steht uns jetzt nicht bloss vermeintlich, sondern wirklich vor Augen und in ihm der Gegenstand selbst, als das, was er ist, d.h. genau so und nicht anders, als wie er in dieser Erkenntnis gemeint ist: als Träger dieser Eigenschaften als Glied dieser Relationen u. dgl.⁵

This passage, with its many striking metaphors, is as good as any in calling attention to what sometimes happens when we assert such a truth as *modus barbara* or “dass die drei Höhen eines Dreieckes sich in einem Punkte schneiden” (Husserl 1913: 2:44). I doubt that anybody could in truth say that he has never experienced “Erkenntnis im strengsten Sinne.” If he is inclined toward scepticism, he may get rid of that experience relating to a particular assertion, but in extricating himself from what he considers an illusion of absolute or apodictic knowledge, he runs the risk of having a new experience of the kind he just subjected to scrutiny.

On the other hand, there is nothing in Husserl’s description that eliminates the possibility of mistaking knowledge of less than the strictest kind for a piece of knowledge of the strictest kind. The history of pure mathematics and rejected doctoral theses both illustrate this point. There is nothing in the description of how we arrive at and judge apodictic knowledge that can help people who do not *really* have a *Sachverhalt wirklich vor Augen* but are fully convinced that they do.

From this I conclude that it is not possible to describe the intimate meeting of human beings with the *Sachverhalt* in such a way that it can be effectively described for the benefit of those who doubt that they have the power to distinguish those meetings from others.

Husserl seems to rely not so much on the description of the crucial meeting as on the exemplifications. He points to assertions that are apt to cause such meetings if grasped in their exact meaning. Of such examples he offers us many: “allgemein gilt für beliebige Klassentermini A, B, C, dass, wenn alle A B und alle B C sind, auch alle A C sind”; “Die drei Höhen eines Dreieckes schneiden sich in einem Punkte”; “Zwei kontradiktorische Sätze sind nicht beide wahr”; and others referred to by names such as *der Bernoullische Schluss von n auf n+1*. A list of these examples, together with a

list of examples of assertions that should not cause the crucial happening—let us say, “One cannot at the same time believe and not believe in the same proposition,” and others—might furnish a kind of test similar to certain color tests.

The appeal to examples that actualize the meeting as a happening is based on the assumption that they are definitively established and that their exact meaning can be communicated to the reader. If the reader does not grasp the exact meaning, but believes he does, and therefore also believes he experiences the crucial meeting, he may be misled permanently. He will try to fix his experience in his memory and use it as a standard. He will use it in judging future assertions, thus perverting whatever ability he once had to discern knowledge of the strictest kind from that of the less strict.

Even if he grasps the exact meaning and gets the *Sachverhalt wirklich vor Augen*, this will happen as a matter of fact, as “eine Tatsache, d. i. ein zeitlich Bestimmtes” (Husserl 1913: 1:76). That it happens under certain conditions would constitute *eine reale Notwendigkeit*, not as a strict law in the sense of Husserl. It is not contradictory to suppose that such a meeting never has been granted to any human being, not even to Husserl himself. I am convinced that the supposition is false, but I may be mistaken in my convictions.

Shall we then, as many of the empirically minded would do, dismiss pure phenomenology and the search for apodictic knowledge, for pure intuitive, ideal knowledge?

Yes and no. To be dismissed is the program of a science of *Wissenschaftslehre* in the space of a system of apodictic knowledge. As soon as a science is said to be science of or about something, there is a radical risk of error; it partakes in the imperfections of the sciences of the real.

Not to be dismissed is the invitation of pure phenomenology to explore the ideal, the infinite domain of forms and structures, including the domain of contradictions. This exploration has considerable autotelic value. Husserl was inspired by the *allgemeine Mannigfaltigkeitslehre*, and it certainly is well suited as a stepping-stone toward free engagement in contemplation of mere possibilities of forms and structures, independent of any purpose to create a *Lehre* or science. The field of exploration will include *the domain of the not real, not pretended real, and not contradictory*.

The term *not contradictory* in the last sentence is preferred to such terms as *evident* or *apodictic*, because of the difficulties of obtaining a concept of evidence unconcerned with the real, and because if we obtain it, it is scarcely discernible from a concept of consistency or noncontradiction. Instead of *ideal*, the term *not real* is used, in order to avoid too many associations with certain conceptions of Platonic idealism. The term *real* is used synonymously with “what is as a matter of fact,” using “a matter of fact” for *eine Tatsache, d. i. ein zeitlich Bestimmtes*.

The domain to be explored is, in part, the same, as far as I can see, as the realm of the ideal as conceived by Husserl. It will include pure logic and pure theory of knowledge insofar as they strictly belong to that realm. All truths, those discovered and those undiscovered, belong to the domain. Truth, in the sense of Husserl, “ist über alle Zeitlichkeit erhoben” (Husserl 1913: 1:77). Further, all falsehoods in the sense of *kontradiktorisches Gegenteil einer Wahrheit* will belong to it. They also are *über alle Zeitlichkeit erhoben*.

Let us return to Husserl as the architect of a system.

Husserl conceives his programmatically pure theory of knowledge and his logic as two systems of truths that rigidly exclude other systems as rightful candidates for the same titles. There is, according to Husserl, if I am not mistaken, *one* pure logic, the one apodictically evident. It is obtained directly from the fountain of strict knowledge, the meetings with the *Sachverhalt* in pure intuition. The same exclusiveness holds for his *pure* theory of knowledge. As a system of assertions expressed in human language, it may show variation owing to homonymy. “Die Bedeutungen” as ideal entities would, however, be identical. A law about the real, according to Husserl, is “eine von unzähligen theoretischen Möglichkeiten einer gewissen, obschon sachlich abgegrenzten Sphäre.” A pure logical law is “die eine und alleinige Wahrheit, die jede andersartige Möglichkeit ausschliesst.”⁶

Now, considering the plurality of ways in which formal logic can be built up as a system, and considering how, because of implicit definitions, the *ideale Bedeutungen* of each formula or proposition are dependent on the system as a totality, we have no strong reason to expect any development toward one particular system as *the* system. The question of whether the different systems of signs are really one, considering their *ideale Bedeutungen*, seems incapable of clear formulation. A third body of propositions and

rules would be needed in order to compare systems of *ideale Bedeutungen*. There is not, however, any definite such body that might be singled out as the “correct” one and used as a basis for the comparison. Consequently, there is no reason to expect one definite result of the comparison.

The situation is similar with regard to the postulate of one definite system of pure theory of knowledge. In the domain of the real, different, mutually inconsistent theories may be equally well confirmed. In the domain of the real, a multiplicity of structures is possible, but they are not necessarily inconsistent or even comparable with one another.

Rigid exclusion of reference to the empirically real does not tend to narrow down the range of different systems.

A system of pure knowledge is as such completely indifferent toward any trait whatsoever of human knowledge, in the sense that at no single place in the system is anything implied concerning the question of whether there exists human knowledge and, if it exists, of what kind it is. No reference is made to mathematics and symbolics as actually developed by mathematicians and logicians. All existent systems as actual systems may contain formidable mistakes or exclusively pure truths. The systems are irrelevant insofar as they are real, that is, insofar as they exist as products of an activity—for example, intentions—of human beings.

Husserl’s criticism of psychologism and his emphasis on the *fundamental* difference between real and ideal are taken for granted in this article. So also is his emphasis on evidence of the apodictic variety as a requirement in pure mathematics and logic. The only difference is that we apply the rigid distinction between real and ideal to any historical system erected, for example, by Husserl, and given the attribute “pure.” Those systems are situated on the human side of the *ewig unüberbrückbares* chasm between real and ideal. They are actually intended systems, products of intentional and ideational activity carried out by Husserl and others in the twentieth century. They will be real, and their properties will have some properties that by definition do not belong to the realm of the ideal. They may or may not represent systems of truth. Human thinking sometimes seems to be, sometimes seems not to be adequate to the tasks in hand. There is no one to tell us when it is adequate and when it is not. The judges are members of our own species. We may actually have a great deal of apodictic knowledge, but it cannot be known (in the strict sense of Husserl) that we have.

ZETETICISM

The conception of pure phenomenology as exploration in the ideal does not exclude its use in research in factual science of science, just as G. F. B. Riemann's fantastic exploration of structures with certain analogies to physical geometry, but totally unconcerned with that geometry as a science of the real, has not excluded its usefulness in factual science. On the contrary, this conception of pure phenomenology makes such use more understandable because it is subsumable under a kind of use exemplified since the dawn of geometry and celestial mechanics as exact sciences.

Pyrrhonism Revisited

The Occasional and the Essential Seeker

Investigators are likely to find what they seek or to reject discoverability, asserting incomprehensibility, or to persist investigating. This is perhaps why also, in regard to what is sought in philosophy, some have claimed to have found truth, others have asserted that it is impossible, and still others go on inquiring. Those who are called Dogmatics believe they have found it, thus Aristotle, Epicurus, the Stoics, and some others. The incomprehensibility was argued by Clitomachus, Carneades, and other Academics; but the sceptics keep on searching.¹

(Sextus Empiricus)

Some of my fellow beings are researchers or, simply, searchers. When asked what they are and what they are doing, they honestly speak about what they are trying to find but have not found. When asked about what they implicitly seem already to presuppose having found, they eagerly try to answer my question straightforwardly and with assurance. They try also to describe *exactly* or in *exact* outline or abstract form what they know for certain that they are honestly trying to find (what they “are” looking for), but they fail in this or they tend to think they fail, or they at least discuss the aspect of possible failure in complete seriousness, using the technique of *pro et contra dicere*. It is as if their findings, even as regards their own intentions, are essentially, and not only pro tempore, conceived as tentative, ad hoc, or

This article was reprinted with permission from *Contemporary Philosophy in Scandinavia*, edited by Raymond E. Olson and Anthony M. Paul (Baltimore: The Johns Hopkins University Press, 1972), 393–493.

as hypothetical findings good only as starting points for more systematic and better-focused search. If I ask for their exact intentions, they might throw up their arms, saying, “Ah, you are a phenomenologist! I wish I had time to do research on my intentions!”

This seemingly evasive behavior is frustrating to me when trying to grasp exactly *where they stand*: I wish to find out what they tacitly, but steadily, assume to be definitively true when asking their questions—in short, their presuppositions. For, of course, they *stand*, but just where? Or perhaps “standing somewhere” is just one possibility among several? *Must* we always stand?

A Dialogue Exemplifying a Pyrrhonist Who Does Not Admit His Pyrrhonism

“Surely you presuppose that this stuff here will not explode,” I said to my contemporary Boyle, the “sceptical chemist,” in his laboratory.

“I am completely convinced,” he answered. “Don’t be afraid, there is nothing I hold more certain than this. There will be no explosion.”

“So, in this experiment you *presuppose* that the stuff will not explode?”

“Of course,” he answered.

“But then you also presuppose the truth of a variety of chemical propositions—all those needed to derive the nonexplosiveness.”

“Do not make me laugh,” he answered. “I am, as you ought to know, contributing to the downfall of several of those “truths.” They have too long been taken for granted. Any of them may tumble and fall, at any time.”

I was completely taken aback. “You are completely convinced that an explosion will not take place as that stuff is mixed, but you nevertheless see no decisive arguments for the truth of any of the premises!”

“No decisive argument for the *truth*—but more than enough for my *trust*, my confidence, insofar as it rests on premises!”

“So you only have probabilities!”

“Probabilities? What are they? Perhaps only a pseudoscientific way of reporting about past regularities.”

He was still smiling, unaware of the serious attack on his character that I now found inevitable. “Robert,” I said, “not a single time in any of our

discussions have you found *decisive* arguments for or against the truth of any proposition. You are a Pyrrhonist or zetetic sceptic! *A seeker!*”

My friend’s face darkened. “What nonsense. In research matters I have not found instances of decisive verification or falsification, but there are innumerable truths I *might* believe in. Pyrrhonism as described by Sextus Empiricus is dead. Short, conclusive refutations abound.”

“Forgive me if my memory fails me, but you seem always to have regard for human fallibility—including your own—stressing the difference between firm convictions and truth, between life and philosophy.”

“I firmly believe that this is *my laboratory*.”

“*Is it true* that it is yours?”

“I have absolutely no reason to doubt it.”

“From *that* you infer the truth?”

“Of course not. Truth does not depend on *my* reasons, or anybody else’s. Why should I make that inference? What need is there for infallibility?”

“Could you not admit that, if pressed, you switch from truth-claims to claims that you are convinced, that you do not have reasons or spare time to doubt, that you do not see why you should be in error in the present case, and so on? Pyrrhonism does not oppose conviction if conviction is defined as an implicit attitude of trust.”

“Anyhow, Pyrrhonism is not *my philosophy*. If I have never found decisive arguments for or against the *truth* of a proposition, this fact is only of biographical interest. From a diary of such failures no philosophy can be inferred.”

“Perhaps not, but could the failures *prevent* you from having a philosophy?”

“Perhaps you trust your philosophy, but do not affirm its truth?”²

Here I shall leave my imaginary debate with a sceptical friend. It exemplifies a frequent kind of debate with the not very numerous people whom I would class as “Pyrrhonic in their life and philosophy” but who resent and resist this label. This resistance I find laudable (“why labels?”), but perhaps the resentment is only a reflection of the low quality of descriptions of Pyrrhonism in textbooks. The arguments of the resisters, if carried far enough in long discussions, sometimes only strengthen my belief that I have found Pyrrhonists in the sense of seekers—zetetics. *There are consistent Pyrrhonists*. Looking back, I would tentatively class myself as one between

about 1952 and 1962. Now I find it difficult to decide what I am, or to rediscover the question.

The Pyrrhonist May Be Strongly Attracted to Certain (Dogmatic) Philosophies

The arguments so far published against Pyrrhonism as a philosophy are weak. My motivation in writing this article is simple: there are Pyrrhonists, and they had better come out into the open. The refutations are rather conventional, and for the most part do not reach Pyrrhonism as described by Sextus Empiricus. In no instance are they decisive. Furthermore, being a Pyrrhonist does not exclude having strong philosophical affiliations of other kinds. In antiquity, Pyrrhonists were close to Heraclitus. Pyrrhonists are “seekers,” and in philosophy this implies prolonged working, however tentatively, within definite conceptual frames.

In this short article, I shall introduce some definitions and postulates of Pyrrhonism for the sake of argument:

1. Pyrrhonic philosophy, maximally condensed: decisive arguments are worth looking for, but there seems to be no decisive argument pro or contra the truth of any proposition!
2. A philosophy does not need to contain any truth-claim.
3. True means “that it is so.”
4. I only know that p if “ p ” is true, that is, if it *is* such that p . “I know that p , but p may be false” is not an acceptable position; the claim to know excludes the admission of the *possibility* of failure.³

Some of these sentences admit rather different interpretations. Somewhat different systems result from the selection of different definite sets of interpretations.

“No Decisive Arguments,” the Core of Pyrrhonism, Is an Exclamation, Not a Proposition

Sentence (1), expressing the core of Pyrrhonic philosophy, has the form of a pronouncement, not an assertion. In this, Pyrrhonism may resemble the

philosophy of Socrates, Kierkegaard, and the early Wittgenstein and differ from that of Spinoza or any other philosopher who takes a set of propositions with a truth-claim adequately and basically to express his philosophy. In this respect, Pyrrhonic philosophy, together with certain forms of Buddhist and Western philosophies, is to be classified as nonpropositional.

In adherence to the terminology of Sextus Empiricus, the term *pronouncement* is used when characterizing “sceptical utterances.” The term *exclamations* also might be used.⁴ They signify primarily the Pyrrhonist’s state of mind when confronting the dogmatic in debate.⁵ Secondly, they signify a basic existential attitude toward conceptual thinking. It is an attitude that cannot adequately be expressed by a set of propositions with truth-claim,⁶ but this does not imply that the Pyrrhonists cannot find each other and communicate. Everyday use of language does only marginally *require* pure conceptual thinking, and those engaged in conceptual thinking may have a variety of attitudes toward their own activity. In the long run, the attitudes interfere with the activity, transforming it into something it was not before. This takes place in the maturing sceptic, according to Sextus.

The sceptical exclamations, in Sextus’s terminology, are utterances indicative of something quasi-permanent, a disposition acquired through prolonged development. At this point Pyrrhonic biographies are relevant: one can begin to understand the historical background of the Pyrrhonist’s existential attitude. To the biographies belong the seeking and not finding, the frustrated primary need for a total view or at least a life philosophy with evidently true premises. Then comes the peace of mind in spite of not finding linked, characteristically, to a continuing search. The peace is already there, but human beings (like rats and some other mammals) seem also to engage in seeking as an autotelic activity.

As a classification unit in philosophy, Pyrrhonism is an ideal-typical construction that includes systematized attitudes toward every position in logic, methodology, ontology, epistemology, and other branches of philosophy; and one of ad hoc *epoché* as regards truth, reflecting a more or less complicated *pro et contra* argumentation, depending upon the current beliefs of dogmatists.

Superficial critics have charged Sextus Empiricus with repetitiousness and unnecessary argumentation, such as against *p* when *p* implies *q*, although he has already argued against *q*. Clearly, though, Sextus does not adhere to any definite organon of inference and implication, and, in princi-

ple, he has to visit every corner of every dogmatic philosophy. He cannot eliminate any of them with generalities as a Dogmatic sceptic or “Academician” might do. Moreover, just as clearly, a systematic Pyrrhonic exposition contains arguments in favor of each dogmatic philosophy. To every dogmatic con-argument, at least one Pyrrhonic pro-argument will correspond. Only at a distance has Pyrrhonism a negativist coloration.

According to the Pyrrhonist, adequate expositions of arguments do not add up to a decision of “true” or a decision of “false.” However, because new arguments appear from time to time among dogmatists as well as among Pyrrhonic seekers, and because memory is fallible, no exposition can be classified as “authorized.”

The exposition of argumentations on all philosophical subjects *and* the pronouncement of a general lack of decisive arguments *and*, perhaps, the pronouncement of the “sceptical way” (*agogé*) as one that leads to happiness, characterize Pyrrhonism. I say “perhaps” because one might wish to take the latter pronouncement as part of an inducement to learn about Pyrrhonism rather than as part of it. Sextus tends to the latter view in his famous genetic definition.

If we exclude Pyrrhonism as a philosophy, we shall have to exclude a long list of philosophies that traditionally are conceived to be such, and that fail only to satisfy the arbitrary postulate that a philosophy must contain at least one proposition claimed to be definitely and definitively true.

Even if we exclude Pyrrhonism as a philosophy, however, that does not imply that the Pyrrhonist is not a philosopher. A philosopher may be always “on the way” (emergent, *geworfen*) and may therefore transcend any classification. The Pyrrhonist is always on the way when working out and testing positions, looking for one that will satisfy the criteria of truth, or criteria of these criteria, or questions of still higher metalevels. The way in which he is “on the way” characterizes him just as deeply and consistently as Kantianism may characterize a nonsceptical personality.

Pyrrhonists Incline Toward Absolutistic Concepts of Truth, but Not Toward Absolutistic Requirements of Grounds for Action

From the point of view of ordinary language, it may be asked whether the Pyrrhonist does not impose *pointless* requirements of decisiveness. Does he

really have any idea of what he requires? Could he specify kinds of evidence that, if at hand, would show the truth of a proposition? If the requirements he poses are never realized, why pose them anyway?

The answer to this seems to be that there are different kinds of decisiveness. If I have a choice between *A* and *B*, I may *decide* to choose *A* on grounds different from those of believing in certain truths. The Pyrrhonist may be a rapid chooser, known for his trusting and benevolent attitude, but he *does* have ideas about truth that are such that no one is *guaranteed* to find it even after a long, laborious search or series of deep intuitions. The idea of truth is important to him, and he does not give it up easily. He does not say, “Well, I did not find a single argument decisive all last year, so why not just take at least 5 percent probability to be decisive this year?” Nor does he predict with certainty that the requirements will *never* be realized. Nor does he pretend that his idea of truth amounts to a definite concept of truth.⁷

One crucial point is this: he finds arguments *not good enough* so far. Charged with the contention that he poses extravagant requirements, he neither denies nor admits the charge but listens to the arguments for the contention. They have so far been vaguely circular: the requirements “must” somehow be too severe because there are hardly any arguments that satisfy them. If one eats five cakes, however, and finds that *all* taste bad, this does not make the decision “bad” pointless. Even if one cannot define clearly what is lacking in flavor, it makes sense to refuse to eat them and to wait for cake number 6—as long as one is not overly hungry. If number 6 tastes bad but one eats it, one has lowered the requirements not of goodness but of acceptance. The sceptic feels that he might accept an argument as pragmatically conclusive, deciding to act upon it, but not necessarily as decisive for *truth*.

Does the Pyrrhonist really retain an absolutistic concept of truth that is artificially separated from concepts of validity, evidence, verification, reasonableness, and tenability?

There are certain reasons to suppose that this is the case. According to Sextus Empiricus, Pyrrhonism does not exclude trust and confidence. Is this not, then, to believe in truths, at least in an unsophisticated way?

To believe strongly and consistently that such and such, to be confident and trust that such and such, seems somehow to be consistent, accord-

ing to Pyrrhonism, with an attitude of *epoché* toward the truth of such and such.

The exclamation “There are no decisive arguments for or against the truth of any proposition!” refers also to propositions of the kind “A is more probable than non-A.” Otherwise it would be probabilism, not Pyrrhonism. The attitude of trust and confidence cannot therefore be the result of attributing a higher probability to A than to non-A, or vice versa.

One would expect that lack of decisive arguments for or against truth would diminish decisive action and increase mistrust, lack of confidence, vacillation, and doubt. According to Pyrrhonism, this is not necessary; and I think it *is* a removal of the notion of truth from certain other notions that makes decisiveness in action compatible with *isosthenia*.

First, “x is true” is taken in Pyrrhonism to be synonymous with “it is the case that x”—an ontological notion in principle separated from any process of verification or falsification. Second, the claim “to know that x” is emphatically identified with a certain kind of claim of incorrigibility: “I know that x, but possibly x is false” and “it is known that x, but possibly it is not the case that x” are rejected. “x is possibly false, therefore I do not know that x” is accepted. The Pyrrhonist trusts that the claim “x is true” is made with consciousness of its implied postulate of incorrigibility.⁸

This *awareness* of incorrigibility separates Pyrrhonic use (and absence of use) of the term *true* from that of everyday life. It makes it understandable that terms with explicit reference to belief attitudes are preferred: “I believe that x is true,” “I believe that x is the case,” “I feel confident that x,” “I trust that x.”

Even the following expressions might well be used: “I trust that x is true,” “I am confident that x is true,” “I am convinced that x is true.” These expressions would be used *angelikos*, expressive of one’s mind. Thus, one would not blindly accept inferences of these kinds:

Premise: I am confident that x is true.

Conclusion: x is true.

Premise: I am convinced that x is the case.

Conclusion: x is the case.

The Pyrrhonist Is Open in Debates About His Own Presuppositions

According to Aristotle, true statements are statements that say about that which is the case (*esti*) that it is the case, and false statements are those that say about that which is not the case that it is the case. If it is the case that *p*, it *cannot* also be the case that not-*p*.

Suppose a person who is considered a Pyrrhonist is entangled in a discussion on the notion of truth and ends up adhering to a definitely absolutist, nonpragmatic, nonvoluntaristic concept of truth such as that introduced by Aristotle. His stand may then be expressed by propositions with truth-claim, and he would presumably accept as decisive certain pro-arguments for the truth of propositions—for example, “What follows is an adequate definition of truth. . . .”

However, such a development from the Pyrrhonic to the dogmatic posture is most surprising, considering the confusing controversies about truth among dogmatists. What a blind will to believe must be required for someone to settle down with any *definitive* conclusions in this foggy field!

In the mid-1930s there was a strong belief that Alfred Tarski⁹ had given an adequate definition of truth and solved an old problem, but subsequent discussion has left the matter in the air. Exactly *what* does Tarski solve? No clear answer has been given. His definition is said to be adequate, but it is admitted that one requirement of adequacy is some sort of agreement with ordinary use. There is, however, no agreement as to how one decides which use is ordinary. Even if the Pyrrhonist must be expected to interest himself vividly in the possibility that he somehow presupposes a nonpragmatic, absolutist notion of truth, his very openness to various approaches in contemporary discussion has so far frustrated his efforts to find decisive arguments.

In general, the Pyrrhonist today, perhaps more than at the time of Sextus Empiricus, will stress an argument against dogmatists who say that the very attitudes and the questions involved in ordinary debate *presuppose* the acceptance of certain propositions *as true* and therefore presuppose at least one decisive argument. The trend of increased belief in transcendental philosophy has made the maxim “There *must* be fundamental presuppositions!” more influential. When concrete instances are offered, however,

they seem to depend on specific approaches in the philosophy of language and epistemology that are controversial, since they lack decisive empirical and intuitive support. At best, they are research programs. Therefore, I do not see how the Pyrrhonist could easily be converted into a dogmatist by prolonged discussions of epistemological presuppositions. Quite the contrary: discussions of such presuppositions tend to promote scepticism.

Furthermore, it is a long road from the discovery and clarification of a presupposition to its acceptance in the form of a true proposition. The form of rule, postulate, norm, or the like is more likely to be adequate. The Pyrrhonist, though, is still without truth-claims.

A Whole Doctrine or Philosophy Is Postulational if There Is at Least One Postulate at Its Foundation

In general, if the verification of a body of beliefs presupposes the acceptance of at least one rule or postulate among a group of conflicting ones, the whole body of propositions corresponding to the beliefs acquires postulational or regulative status. At best, our conclusion will be of the form “The propositions are true if the postulate or rule is accepted.” From this alone, “The propositions are true” does not follow.

No Proposition Is Neutral Toward a System: Is Grass Really Green?

We now arrive at the crucial point of this article: the relevance of systems to Pyrrhonism. Among professional philosophers today there are of course many attitudes toward philosophical systems. My own point of view (stated elsewhere) is highly positive, because I consider the autonomy of the sciences and that of so-called common sense to be an illusion. I understand a full systematic philosophy to be a synthesis of a logic, a methodology, an ontology, an epistemology, a philosophy of history, an axiology, and (normative) ethics. To *publish* in all these fields is of course a hazardous undertaking, but I take it to be normal among philosophers to have or *seek* such a synthesis. A philosophy in this sense interacts with one’s way of seeing and experiencing life, the universe, and oneself.

The distinction between “in itself” and “in something else” (*in se, in*

alio) is fundamental in Spinoza's system.¹⁰ Substance, cause, freedom, wisdom, joy, passion, goodness, perfection, slavery, democracy—all are conceived in terms of distinction. It colors the perception of everything and therefore affects the meaning of any proposition in the system. A follower of Spinoza is therefore more easily exposed to scepticism: it is enough to doubt the meaningfulness of the fundamental distinction. Belief in systems favors the emergence of scepticism.

Let us for a moment return to the opening quotation from Sextus Empiricus. Sceptics and Dogmatists are there defined *only* in relation to "what is sought in philosophy." If questions of science or common sense were independent of philosophical questions, therefore, Pyrrhonism would be a partial scepticism, on a par with religious or historical scepticism. The idea of systems in which every question is placed in a conceptual framework, and of the explicitness of the fundamental assumptions and postulates that are therefore required, enlarges partial scepticism into total scepticism.

I do not see that *any proposition whatsoever* can be completely neutral toward differences in systems, and this makes a genuine seeker of a system normally indecisive with regard to the truth-value of any proposition.

Exceptions are platitudes such as "grass is green"—expressive, perhaps, of the kind of dumbness, sluggishness, or conventionality of perception of which painters and other artists try more or less in vain to cure us. If taken seriously as propositions, such formulas become nonneutral toward conceptual frameworks and therefore toward differences in philosophical systems.

Sextus's stock example is not "grass is green" but "honey is sweet." It is his contention, as I understand him, that efforts to conceptualize this utterance soon meet the formidable question of whether the sweetness is in the honey or not.¹¹ The problem area of secondary and tertiary qualities is relevant, and here evidence is scarce and meaning obscure.

When a person affirms that he is a logical empiricist, a liberal, and an admirer of Beckett, he does not mean to say that in his mind there is every second a recognizable manifestation of logical empiricism, liberalism, and admiration of Beckett. Most people would agree to this. On the other hand, if somebody tentatively affirms that he might be a philosophic sceptic, there tends to be an immediate outcry: insincere! pointless! inconsistent!, or the requirement is laid down that he must then doubt *everything at*

once—not assume, presume, trust, or believe anything even for a split second. (See: “Now you are just eating fish. But if, as you say, you are an admirer of Beckett’s, *turn on immediately* and stop doing anything else!”) What is characteristic of a Pyrrhonist, however, is a disposition, a structure of traits that manifests itself in the long run, not a split-second reaction. This colors, for example, his assumptions; these acquire the character of posits, not assertions with truth-claim. To assess a truth-claim that involves a whole system, the Pyrrhonist must let himself sink deeply into it. This requires time and an openness that is inconsistent with a continuous flow of doubt, vacillation, and counterargumentation running through his mind. One may hear a dogmatist say, “He is supposed to be a sceptic, but he has been arguing enthusiastically in favor of Heraclitus all year!” It is of course suspicious to act like this for a whole year. The long time it takes to manifest a sceptical pattern of thought makes it always relevant to ask, as colleagues of sceptics have done since Pyrrho, Is he not really a Heraclitean, or an empiricist, or . . . ? However, trying to balance argument *pro et con* every minute is bad research heuristic. Nothing decisive can be inferred from temporary imbalances.

Tentative Conclusions

1. Pyrrhonism as a personal philosophy is neither inconsistent nor psychologically impossible.
2. A Pyrrhonist undertaking a systematic inquiry assumes, presupposes, and uses postulates, but he does not assume the truth of any proposition. He posits, takes for granted until further notice, and acts upon “natural, spontaneous beliefs,” but he does not affirm, or feel inclined to affirm, any truths. Among his spontaneous beliefs are some on the metalevel concerning notions of truth.
3. He does not “resist” what seems obvious at the moment, but he finds it difficult to decide for or against as soon as an utterance is made more precise by means of a set of conceptual distinctions.
4. One may speak of a Pyrrhonic attitude in a psychological sense, but it is not to be identified with doubt. There is also a searching *Einstellung*, way of being, of existential import, which as a personal philosophy tran-

scends the mere psychological, just as does Kantianism or any other philosophy that a person “has.”

5. A philosophy, insofar as it tends toward a total view, colors everything. Therefore, indecision with regard to its truth is an indecision as to truth-value in general. One kind of genesis of a Pyrrhonist may therefore be that of a seeker who, after having delved deeply into two different possibilities of total views, finds arguments for or against in part indecisive, in part irrelevant.

Trust and Confidence in the Absence of Strict Knowledge and Truth: An Answer to Nicholas Rescher's Critical Reappraisal of Scepticism

Distinction Between the Academic and the Pyrrhonic Sceptic

What is scepticism and what are the main arguments for and against it? As happens so often, we have to admit that it depends in part on what is meant by the word. The history of various usages of the word, and closely corresponding words in some other languages, goes back more than 2,000 years. An argument against "scepticism" in one sense may be irrelevant, or even a pro-argument, in relation to "scepticism" in another.

I do not believe that this is a trivial point. Even today, one cannot say that the scepticism discussion is a net discussion—*net* used as in "net income," that is, when misunderstandings owing to differences of terminology are cleared away. The Greek verb *sképtomai* (to look about, look carefully at, view, examine) was used when the expression "medical scepticism" was coined—the medical tradition in which Hippocrates is the greatest name—stressing empirical observation and abstention from the application of philosophical and mythological theories. Make experience and application of carefully tested procedures your guide! Never *rely* on a theory!

A distinction worked out in detail by the greatest author on scepticism, Sextus Empiricus, plays a crucial role in what follows in this article. He distinguished between the view that, strictly speaking, knowledge and truth cannot be found, and the view that, strictly speaking, so far no piece of knowledge or truth has been found, but some people are still looking for it. Philosophers claiming to have found truth (or at least one truth) he calls Academic and those who think they have not found any, but still are on the

This article was written in 1994. It is being published here for the first time.

lookout, he calls Pyrrhonic after the philosopher Pyrrho. Clearly, Sextus's usage is rather different from what people today generally associate with the word *sceptic*.

In the vernacular a sceptic tends to be one who is prone to turn down proposals to act or to value something positively. He is a doubter, embracing doubt as a general attitude, or in a special case. To appreciate scepticism as a cluster of traditions in the history of philosophy, one must have some interest in claims and concepts of truth and knowledge.

A Story About the Problems of Using the Terms *Truth and Knowledge*

We prepare for a voyage across water, but of course without knowledge about the weather we shall face. At best, we have the assurances of a meteorologist that our prospects are excellent. Experts have tested our little boat, but they make it clear that they take no responsibility. They tell us that every scientific and technical detail has been carefully considered—all is in order, but anything can happen anyhow. We have remote possibilities. For example, the day we set sail, the Atlantic could disappear. The game has had an effect that we should have anticipated: we do not use the term *knowledge* any longer. We have a lot of confidence in our undertaking, but remote possibilities of error are regarded as sufficient reason not to use the knowledge and truth terminology. For example, we don't like to say "Yes, I know that . . . , but I may be wrong" or "Sure, we know that . . . , but it may be a mistake."

If something is known, it *is* the case, it *is* true, it *is* so. It is nonsense to make any further inquiry. If we know we are not yet on the water but on land, it is true that we are on land; it is the case that we are on land, "it *is* so"—as many people who are not philosophers would say.¹ If we know something, we can *guarantee* that it is so.

We *trust* that we will not meet terrible weather, overwhelming waves, a typhoon where there never has been a typhoon, a gigantic whale carrying us away in a wrong direction, asking us to be kind to its smaller relatives. We are not suspicious, not doubters, nor dogmatists. We have confidence, but no knowledge.

The Logic of Knowledge Leads to Scepticism

Let me first admit that I belong to the group that has had trouble using the terms *knowledge* and *truth*. In what follows I'll talk more about us. We all *tend* to, or have *tended* to, avoid expressions such as "I know that" and "It is known that." We have even tended to avoid their use in situations in which most people would find it ridiculous or completely unfounded not to use those expressions. I have done this, for example, in discussions with professors of philosophy. I mention but do not use the terms. On the metalevel—where we shall now talk about whether we ever know anything in the strict sense—if we know something, then it is true, and we know that it is true. Sometimes we are asked, Don't you know so and so? by people who use the term very loosely in ways we do not like. Even if the possibility of error is clear, it is socially warranted to say "Yes, I know." In court, as a witness, it may even be ethically wrong to say "No, I don't *know* so" or "Strictly speaking, I don't know, but I am confident it is so." Broader usages are the normal or general way of speaking. That something turns out to be a mistake is often taken very lightly. One does not risk one's reputation by using the term loosely.

You see, we can easily get into trouble in our community if we stick to our preferred use of such expressions as "I know that . . . ," "It is true that . . . ," "What do you advise us to do?" Let me insert here something about the logic of knowledge as exposed in Nicholas Rescher's superbly clear and well-documented book *Scepticism: A Critical Reappraisal* (1980). I have a special reason to go into this book in detail because it is generously dedicated to me—"For (though also against) Arne Naess." Rescher lists five "patently valid principles of the 'logic' of knowledge." Numbers 1 and 5 may be formulated thus, with the letter *p* used for an assertion.

1. If *p* is a piece of knowledge, *p* is true.
5. If *p* is a piece of knowledge, then there cannot be any assertion *q* such that if *q* is true then *p* is false.

The first principle Rescher (1980: 251) calls The Veracity of Knowledge; the fifth, *very important principle*, The Irrefutability of Knowledge. In short, if something is known, it is true, it is simply the case, and therefore it cannot possibly be refuted.

I agree with Rescher that those two if-then principles are “patently valid principles” of the logic of knowledge when the term *knowledge* is taken in a definite, strict sense, and not in a loose, broad sense. In what follows I refer to Rescher’s sense as “the strict sense of knowledge,” and when I write *knowledge*, *to know*, and so on, I always refer to the strict sense, if I do not explicitly say that I refer to a loose sense.

Suppose now that *A* is the name of a person. By “*A* is a mild sceptic” and “*A* favors mild, personal scepticism” I mean the same as “*A* thinks that he or she does not know anything in the strict sense.”

Some well-informed people will say that the scepticism referred to is only a detail of an autobiography and not a philosophy of scepticism. I disagree: it may be part of a philosophy; the person may have studied the philosophers’ proposals of what certainly are pieces of knowledge, and may have argued against the proposals as unconvincing. They have not helped *A* to find a piece of knowledge. He disagrees with the philosophers studied in the sense that, after some argumentation in relation to each proposal that an assertion *p* is a piece of knowledge, he concludes that “I do not find *p* to be a piece of knowledge.” This is plainly a part of philosophical discussion—at least as conceived by Rescher in his book.

Rescher generously ends his book with this positive judgment:

Much essential clarification of the nature of knowledge can only be attained by analyzing how the key arguments deployed by the sceptic fail in the final analysis to establish his governing conclusion of the illegitimacy of claims to knowledge.

(Ibid., p. 250)

The unattainability of knowledge is a “dogmatic” thesis of the so-called Academic sceptic, according to Sextus Empiricus (*Pyrrhon.*, 1,1,1). Rescher mentions Sextus six times in his book, and nowhere does he intimate that Sextus stands for an inferior or nonphilosophical scepticism. As I interpret Rescher’s point of view, it is compatible with that of Sextus, as I interpret the latter. It seems, however, that Rescher does not agree. Interpretation is a delicate affair and I find it indispensable to quote Rescher on the matter:

The sceptic prefers to characterize his opponents as *dogmatists*. But the use of this pejorative term distorts the issue. A dogmatist is not simply someone who claims to *know* something, but one who closes his mind on the issue—

who refuses to entertain objections and heed difficulties. Accordingly, we have adopted the term *cognitivist* to designate the sceptic's opponent. The cognitivist crosses the threshold into dogmatism only if he maintains that once we claim knowledge we "close the book" on the matter and take the stance that under no circumstances or conditions would we ever retract such a claim. The position to be developed here does not take this dogmatic stance. It propounds a fallibilist theory of factual knowledge which recognizes that in principle a perfectly valid claim to knowledge may have to be withdrawn in the light of "unforeseen developments."

(Ibid., p. 3)

It is, as I see it, of crucial importance how we understand the withdrawal of the claim to know that such and such. Is it not an admission that we did *not* know? The *claim* may have been amply justified, but we did not know what we thought we knew. Principle 5 implies that there could not be valid arguments for a withdrawal if we *really* knew.

The Greek norm and adjective *dogmatikói* does not imply closedness of mind or refusal to consider objections. A "dogma" is in most contexts "an opinion," "a thesis," "a doctrine." Sextus mentions Aristotle as an example of a dogmatic. For Sextus it is enough that they claim to have found and established at least one truth in a strict sense of the Rescher kind. If fallibilism is taken to refer to all assertions, Sextus is a fallibilist. (Tautologies are not counted because if a sentence asserts nothing—for example, "If it is raining, it is raining"—I don't conceive it to be true or false or express knowledge.)

As I shall discuss later in detail, Sextus's zetetic sceptic may use sentences of the kind "I know that such and such" and "It is true that such and such," using the terms loosely and according to social conventions. The *claim* to know may be said to be valid according to the standards of the community. That is, one is justified in claiming that one knows such and such. Calling an assertion made by myself a truth or knowledge claim, I assert that something is true or a piece of knowledge, but saying that somebody else claims such and such to be true or a piece of knowledge does not imply that I agree. That I find the claim justifiable does not imply that I agree. "Under the circumstances I find Mr. A's claim that such and such is the case fully justifiable. No information was available that should make him doubtful." I have the feeling that Rescher does not always distinguish truths and truth-claims as consistently as I think is necessary.

Sextus discusses mathematics and logic at length. It is not necessary, I

think, to go into that much detail here. It may suffice to say that the areas of assertion covered by a zetetic sceptic include every assertion that is not a tautology.

If a claim to knowledge “may *have to* be withdrawn”—for example, that a certain gun at a certain moment was unloaded—I think it amounts to a falsification. That is, what was claimed to be a piece of knowledge was not such a piece, but a mistake. It seems that Rescher here is very, very close to the opinion that there is no empirical knowledge, no assertion that fulfills principle 5. “Unforeseen developments” implies unforeseen refutability. Or one has to show that in relation to certain empirical assertions, there can be no unforeseen developments, no new discoveries, no possible sources of misunderstanding or error. How are we able to do that?

In short, it seems that Rescher’s cognitive position is compatible with Sextus’s zetetic scepticism, and therefore also with my own scepticism: we have no guarantees in the strict sense as to what will happen in the next moment. This also applies, of course, to what we will think in the next moment. It touches every belief we have about the past. In this way the *openness of the mind* covers the past. Such a view is apt to influence our total view, if we can be said to have any: our view of the cosmos, ourselves, our duties, our lifestyle priorities, are all affected. Perhaps only mildly?

What about the highly professional arguments against scepticism that we find in Rescher’s book? I have evidently not delved into the matter as carefully as it deserves.

A crucial concept in Rescher’s system is that of a language community. To withdraw from the community is a serious thing, but to me it is not clear how Rescher makes a withdrawal decisive in his “critical appraisal of scepticism.”

Let me quote from my book what to Rescher (1980: 74) seems “quite wrong”:

If I hesitate in, or abstain from, saying “I know it” because I see (am sure I see) a *remote possibility* of being wrong, this does not necessarily violate any explicit or implicit rules of ordinary language. It may be a symptom of overcautiousness, hypochondria, hyperactivity of the imagination, or inability to square up to some formidable responsibility, but . . . I am still a member of my *language* community.

(Naess 1968: 124 [SWAN II])

The reason for Rescher's disagreement resembles those of proponents of tyrannical *Gleichshaltung*. He writes, "Nevertheless, this seems quite wrong. For in the specific regard at issue, I have (to this extent) *withdrawn* from the community in abandoning the standards that govern its practices. To refuse to countenance what *they* call knowledge as *my* 'knowledge' is as serious—and deviant—as to refuse to countenance what *they* call dogs as deserving of this appellation from my variant point of view" (Rescher 1980: 74).

The term *govern* is too strong. There are regulations in the usages of "I know that . . ." but not laws such as gravitation.

In a community of a hundred people all except one might use the expression "I know that . . ." in a certain situation. The one abstains because he or she feels sure of a remote possibility of being mistaken. This person is still a member of the language community. He may add, "I refuse to say that I know because I clearly see a remote possibility that I am mistaken." This remark does make it more obvious why he might feel an outsider, but also that he does belong to the language community. Or perhaps it is here a question of how to define a community. There are differences in tightness of communities, of *Gleichschaltung*. In a fairly open community, one may notice that a certain person uses "I promise" and "I know" much too freely, *but* communication is not seriously disturbed because of that.

That *Knowledge* Is Sometimes Used in a Strict and Sometimes in a Loose Sense Does Not Affect Communication Seriously

Suppose somebody, *B*, comes back to my community, *C*, from a long stay in the Arctic, with an animal, Peter, and suppose other members of *C* refer to it as "the dog Peter." Let us inspect three dialogues within *C*:

I

1. A: Your dog is extraordinarily expressive in the way it salutes people and other dogs.
2. B: Peter is not a dog.
3. A: It *is* a dog.
4. B: It has the following characteristics: . . .

ZETETICISM

5. A: Aha, then I agree. Peter is *not* a dog. It is a wolf.

II

As in (I) except for the following changes:

5.a. A: Then it is a dog according to our terminology in *C*.

6.a. B: It is a wolf according to mine.

7.a. A: At least we agree about the characteristics, but you have left our language community.
